AMD makes no representations or warranties with respect to the accuracy or completeness of the contents of this publication and reserves the right to discontinue or make changes to products, specifications, product descriptions or documentation at any time without notice. The information contained herein may be of a preliminary or advance nature. No license, whether express, implied, arising by estoppel, or otherwise, to any intellectual property rights is granted by this publication. Except as set forth in AMD's Standard Terms and Conditions of Sale, AMD assumes no liability whatsoever, and disclaims any express or implied warranty, relating to its products including, but not limited to, the implied warranty of merchantability, fitness for a particular purpose, or infringement of any intellectual property right.

AMD's products are not designed, intended, authorized or warranted for use as components in systems intended for surgical implant into the body, or in other applications intended to support or sustain life, or in any other application in which the failure of AMD's product could create a situation where personal injury, death, or severe property or environmental damage may occur. AMD reserves the right to discontinue or make changes to its products at any time without notice.

Trademarks

AMD, the AMD Arrow logo, and combinations thereof are trademarks of Advanced Micro Devices, Inc.

Dolby is a trademark of Dolby Laboratories.

HDMI is a trademark of HDMI Licensing, LLC.

HyperTransport is a licensed trademark of the HyperTransport Technology Consortium.

Microsoft and Windows are registered trademarks of Microsoft Corporation.

MMX is a trademark of Intel Corporation.

PCI Express and PCIe are registered trademarks of PCI-Special Interest Group (PCI-SIG).

Other product names used in this publication are for identification purposes only and may be trademarks of their respective companies.

Dolby Laboratories, Inc.

Manufactured under license from Dolby Laboratories.

Rovi Corporation

This device is protected by U.S. patents and other intellectual property rights. The use of Rovi Corporation's copy protection technology in the device must be authorized by Rovi Corporation and is intended for home and other limited pay-per-view uses only, unless otherwise authorized in writing by Rovi Corporation.

Reverse engineering or disassembly is prohibited.

USE OF THIS PRODUCT IN ANY MANNER THAT COMPLIES WITH THE MPEG-2 STANDARD IS EXPRESSLY PROHIBITED WITHOUT A LICENSE UNDER APPLICABLE PATENTS IN THE MPEG-2 PATENT PORTFOLIO, WHICH LICENSE IS AVAILABLE FROM MPEG LA, L.L.C., 6312 S. FIDDLERS GREEN CIRCLE, SUITE 400E, GREENWOOD VILLAGE, COLORADO 80111.

Disclaimer

While every precaution has been taken in the preparation of this document, Advanced Micro Devices, Inc. assumes no liability with respect to the operation or use of AMD hardware, software or other products and documentation described herein, for any act or omission of AMD concerning such products or this documentation, for any interruption of service, loss or interruption of business, loss of anticipatory profits, or for punitive, incidental or consequential damages in connection with the furnishing, performance, or use of the AMD hardware, software, or other products and documentation provided herein. Ensure that you have the latest documentation.

Table of Contents

1	Overview	20
1.1	Intended Audience	20
1.2	Reference Documents	20
1.3	Conventions	20
1.3.1	Numbering	20
1.3.2	Arithmetic And Logical Operators	21
1.3.3	Operator Precedence and Associativity	22
1.4	Definitions	22
1.5	Changes Between Revisions and Product Variations	27
1.5.1	Revision Conventions	27
1.5.2	Major Changes	28
1.5.2.1	Major Changes to Core/NB Performance Counters	28
2	Functional Description	28
2.1	Processor Overview	28
2.2	System Overview	29
2.3	Processor Initialization	29
2.3.1	BSC Initialization	30
2.3.2	AP Initialization	30
2.3.3	Using L2 Cache as General Storage During Boot	30
2.3.4	Instruction Cache Configuration Register Usage Requirements	32
2.4	Core	32
2.4.1	L2 complex	32
2.4.2	Caches and TLBs	33
2.4.2.1	Registers Shared by Cores in a L2 complex	33
2.4.3	Virtual Address Space	33
2.4.4	Processor Cores and Downcoring	34
2.4.4.1	Software Downcoring using D18F3x190[DisCore]	34
2.4.5	Physical Address Space	35
2.4.6	System Address Map	35
2.4.6.1	Memory Access to the Physical Address Space	35
2.4.6.1.1	Determining Memory Type	35
2.4.6.1.2	Determining The Access Destination for Core Accesses	35
2.4.7	Timers	36
2.4.8	Interrupts	36
2.4.8.1	Local APIC	36
2.4.8.1.1	Detecting and Enabling	36
2.4.8.1.2	APIC Register Space	37
2.4.8.1.3	ApicId Enumeration Requirements	37
2.4.8.1.4	Physical Destination Mode	37
2.4.8.1.5	Logical Destination Mode	37
2.4.8.1.6	Interrupt Delivery	38
2.4.8.1.7	Vectored Interrupt Handling	38
2.4.8.1.8	Interrupt Masking	38
2.4.8.1.9	Spurious Interrupts	38
2.4.8.1.10	Spurious Interrupts Caused by Timer Tick Interrupt	39
2.4.8.1.11	Lowest-Priority Interrupt Arbitration	39
2.4.8.1.12	Inter-Processor Interrupts	39

2.4.8.1.13	APIC Timer Operation	40
2.4.8.1.14	Generalized Local Vector Table	40
2.4.8.1.15	State at Reset	40
2.4.8.2	System Management Mode (SMM)	40
2.4.8.2.1	SMM Overview	40
2.4.8.2.2	Operating Mode and Default Register Values	41
2.4.8.2.3	SMI Sources And Delivery	41
2.4.8.2.4	SMM Initial State	41
2.4.8.2.5	SMM Save State	42
2.4.8.2.6	Exceptions and Interrupts in SMM	47
2.4.8.2.7	The Protected ASeg and TSeg Areas	47
2.4.8.2.8	SMM Special Cycles	47
2.4.8.2.9	Locking SMM	48
2.4.8.2.10	Synchronizing SMM Entry (Spring-Boarding)	48
2.4.9	Secure Virtual Machine Mode (SVM)	49
2.4.9.1	BIOS support for SVM Disable	49
2.4.10	CPUID Instruction	50
2.4.10.1	Multi-Core Support	50
2.5	Power Management	51
2.5.1	Processor Power Planes And Voltage Control	51
2.5.1.1	Serial VID Interface	51
2.5.1.1.1	SVI2 Features	52
2.5.1.2	Internal VID Registers and Encodings	52
2.5.1.2.1	MinVid and MaxVid Check	52
2.5.1.3	Low Power Features	52
2.5.1.3.1	PSIx_L Bit	52
2.5.1.3.1.1	BIOS Requirements for PSIO_L	53
2.5.1.3.2	Low Power Voltages	54
2.5.1.4	Voltage Transitions	54
2.5.1.4.1	Hardware-Initiated Voltage Transitions	54
2.5.1.4.2	Software-Initiated Voltage Transitions	55
2.5.1.4.2.1	Software-Initiated NB Voltage Transitions	55
2.5.2	Frequency and Voltage Domain Dependencies	55
2.5.2.1	Dependencies Between Cores	55
2.5.2.2	Dependencies Between Subcomponents on VDDNB	55
2.5.2.3	BIOS Requirements for Power Plane Initialization	56
2.5.3	CPU Power Management	56
2.5.3.1	Core P-states	56
2.5.3.1.1	Core P-state Naming and Numbering	56
2.5.3.1.1.1	Software P-state Numbering	57
2.5.3.1.1.2	Hardware P-state Numbering	57
2.5.3.1.2	Core P-state Control	57
2.5.3.1.3	Core P-state Visibility	58
2.5.3.1.4	Core P-state Limits	58
2.5.3.1.5	Core P-state Transition Behavior	59
2.5.3.1.6	BIOS Requirements for Core P-state Initialization and Transitions	59
2.5.3.1.7	Processor-Systemboard Power Delivery Compatibility Check	60
2.5.3.1.8	BIOS COF and VID Requirements After Warm Reset	62
2.5.3.1.8.1	Core Maximum P-state Transition Sequence After Warm Reset	62
2.5.3.1.8.2	Core Minimum P-state Transition Sequence After Warm Reset	62
2.5.3.1.8.3	ACPI Processor P-state Objects	63

2.5.3.1.8.4	Fixed ACPI Description Table (FADT) Entries	64
2.5.3.1.8.5	XPSS (Microsoft Extended PSS) Object	64
2.5.3.2	Core C-states	64
2.5.3.2.1	C-state Names and Numbers	65
2.5.3.2.2	C-state Request Interface	65
2.5.3.2.3	C-state Actions	65
2.5.3.2.3.1	C-state Probes and Cache Flushing	65
2.5.3.2.3.2	Core C1 (CC1) State	66
2.5.3.2.3.3	Core C6 (CC6) State	66
2.5.3.2.3.4	Package C6 (PC6) State	66
2.5.3.2.4	C-state Request Monitors	67
2.5.3.2.4.1	FCH Messaging	67
2.5.3.2.4.2	Cache Flush On Halt Saturation Counter	67
2.5.3.2.5	Exiting C-states	67
2.5.3.2.6	ACPI Processor C-state Objects	68
2.5.3.2.6.1	_CST	68
2.5.3.2.6.2	_CRS	68
2.5.3.2.6.3	Fixed ACPI Description Table (FADT) Entries	68
2.5.3.2.7	BIOS Requirements for Initialization	68
2.5.3.3	Effective Frequency	68
2.5.4	NB Power Management	69
2.5.4.1	NB P-states	69
2.5.4.1.1	NB P-state Transitions	69
2.5.4.1.2	BIOS NB P-state Configuration	70
2.5.4.1.2.1	NB P-state COF and VID Synchronization After Warm Reset	70
2.5.4.1.2.2	NB P-state Transitions	71
2.5.4.1.2.3	NB P-state Configuration for Runtime	71
2.5.4.2	NB C-states	71
2.5.5	Bandwidth Requirements	72
2.5.6	GPU and Root Complex Power Management	72
2.5.6.1	Dynamic Power Management (DPM)	72
2.5.6.1.1	Activity Monitors	72
2.5.6.1.2	SCLK DPM	72
2.5.6.1.3	LCLK DPM	73
2.5.6.2	GPU and Root Complex Power Gating	73
2.5.7	DRAM Power Management	74
2.5.7.1	Memory P-states	74
2.5.7.2	DRAM Self-Refresh	74
2.5.7.3	Stutter Mode	75
2.5.7.3.1	System BIOS Requirements for Stutter Mode Operation During POST	75
2.5.7.4	EVENT_L	75
2.5.8	System Power Management	75
2.5.8.1	S-states	75
2.5.8.1.1	ACPI Suspend to RAM State (S3)	75
2.5.9	Application Power Management (APM)	76
2.5.9.1	Core Performance Boost (CPB)	76
2.5.9.1.1	C-state Boost	77
2.5.9.2	TDP Limiting	77
2.5.9.3	Bidirectional Application Power Management (BAPM)	77
2.6	Performance Monitoring	78
2.6.1	Performance Monitor Counters	78

2.6.1.1	Core Performance Monitor Counters	78
2.6.1.2	L2I Performance Monitor Counters	78
2.6.1.3	NB Performance Monitor Counters	79
2.6.2	Instruction Based Sampling (IBS)	79
2.7	Configuration Space	80
2.7.1	MMIO Configuration Coding Requirements	80
2.7.2	MMIO Configuration Ordering	81
2.7.3	Processor Configuration Space	81
2.8	Northbridge (NB)	81
2.8.1	NB Architecture	81
2.8.2	NB Routing	82
2.8.2.1	Address Space Routing	82
2.8.2.1.1	DRAM and MMIO Memory Space	82
2.8.2.1.2	IO Space	82
2.8.2.1.3	Configuration Space	82
2.8.2.1.3.1	Recommended Buffer Count Settings Overview	83
2.8.3	Memory Scrubbers	83
2.9	DRAM Controllers (DCTs)	84
2.9.1	Common DCT Definitions	84
2.9.2	DCT Frequency Support	85
2.9.3	DCT Configuration Registers	88
2.9.4	DDR Pad to Processor Pin Mapping	89
2.9.4.1	DDR Chip to Pad Mapping	89
2.9.5	DRAM Controller Direct Response Mode	90
2.9.6	DRAM Data Burst Mapping	90
2.9.7	DCT/DRAM Initialization and Resume	92
2.9.7.1	Low Voltage DDR3	92
2.9.7.2	NB P-state Specific Configuration	93
2.9.7.3	Memory P-state Specific Configuration	93
2.9.7.4	DDR Phy Initialization	94
2.9.7.4.1	Phy Voltage Level Programming	94
2.9.7.4.2	DRAM Channel Frequency Change	94
2.9.7.4.2.1	Requirements for DRAM Frequency Change During Training	95
2.9.7.4.3	Phy Fence Programming	96
2.9.7.4.3.1	Phy Fence Training	97
2.9.7.4.4	Phy Compensation Initialization	97
2.9.7.5	SPD ROM-Based Configuration	100
2.9.7.6	Non-SPD ROM-Based Configuration	101
2.9.7.6.1	TrdrdSdSc, TrdrdSdDc, and TrdrdDd (Read to Read Timing)	102
2.9.7.6.2	TwrwrSdSc, TwrwrSdDc, TwrwrDd (Write to Write Timing)	102
2.9.7.6.3	Twrrd (Write to Read DIMM Termination Turn-around)	102
2.9.7.6.4	TrwtTO (Read-to-Write Turnaround for Data, DQS Contention)	103
2.9.7.6.5	DRAM ODT Control	103
2.9.7.6.5.1	DRAM ODT Configuration	104
2.9.7.6.6	DRAM Address Timing and Output Driver Compensation Control	106
2.9.7.7	DCT Training Specific Configuration	114
2.9.7.8	DRAM Device and Controller Initialization	114
2.9.7.8.1	Software DDR3 Device Initialization	115
2.9.7.8.1.1	DDR3 MR Initialization	115
2.9.7.9	DRAM Training	119
2.9.7.9.1	Write Levelization Training	119

2.9.7.9.1.1	Write Leveling Seed Value	120
2.9.7.9.2	DQS Receiver Enable Training	121
2.9.7.9.2.1	DQS Receiver Enable Training Seed Value	122
2.9.7.9.3	DQS Receiver Enable Cycle Training	123
2.9.7.9.4	DQS Position Training	123
2.9.7.9.5	Calculating MaxRdLatency	127
2.9.7.9.5.1	MaxRdLatency Training	127
2.9.7.10	DRAM Phy Power Savings	128
2.9.8	Continuous Pattern Generation	129
2.9.8.1	DCT Training Pattern Generation (Reliable Read Write Mode)	129
2.9.8.1.1	Activate and Precharge Command Generation	129
2.9.8.1.2	Read and Write Command Generation	130
2.9.8.1.3	Configurable Data Patterns	131
2.9.8.1.3.1	Static Data Pattern Override	132
2.9.8.1.3.2	Xor Data Pattern Override	133
2.9.8.1.4	Data Comparison	134
2.9.8.1.4.1	Activate and Precharge Traffic Generation	134
2.9.8.1.5	BubbleCnt and CmdStreamLen Programming	135
2.9.9	Memory Interleaving Modes	136
2.9.9.1	Chip Select Interleaving	136
2.9.10	Memory Hoisting	137
2.9.10.1	DramHoleOffset Programming	138
2.9.11	DRAM CC6/PC6 Storage	139
2.9.11.1	Fixed Storage	139
2.9.12	DRAM On DIMM Thermal Management and Power Capping	140
2.10	Thermal Functions	142
2.10.1	The Tctl Temperature Scale	142
2.10.2	Temperature Slew Rate Control	143
2.10.3	Temperature-Driven Logic	143
2.10.3.1	PROCHOT_L and Hardware Thermal Control (HTC)	143
2.10.3.2	Local Hardware Thermal Control (LHTC)	144
2.10.3.3	Software P-state Limit Control	144
2.10.3.4	THERMTRIP	145
2.11	Root Complex	146
2.11.1	Overview	146
2.11.2	Interrupt Routing	146
2.11.2.1	IOAPIC Configuration	147
2.11.3	Links	147
2.11.3.1	Overview	147
2.11.3.2	Link Configurations	148
2.11.4	Root Complex Configuration	148
2.11.4.1	LPC MMIO Requirements	148
2.11.4.2	Configuration for non-FCH Bridges	148
2.11.4.3	Link Configuration and Initialization	148
2.11.4.3.1	Link Configuration and Core Initialization	149
2.11.4.3.2	Link Training	149
2.11.4.4	Miscellaneous Features	149
2.11.4.4.1	Lane Reversal	149
2.11.4.4.2	Link Speed Changes	150
2.11.4.4.2.1	Autonomous Link Speed Changes	150
2.11.4.4.3	Deemphasis	150

2.11.4.5	Link Power Management	150
2.11.4.5.1	Link States	150
2.11.4.5.2	Dynamic Link-width Control	150
2.11.4.6	Link Test and Debug Features	150
2.11.4.6.1	Compliance Mode	150
2.11.5	BIOS Timer	151
2.11.6	PCIe Client Interface Control	151
2.12	System Management Unit (SMU)	152
2.12.1	Software Interrupts	152
2.13	Graphics Processor (GPU)	152
2.13.1	Graphics Memory Controller (GMC)	152
2.13.2	Frame Buffer (FB)	153
2.14	RAS Features	154
2.14.1	Machine Check Architecture	154
2.14.1.1	Machine Check Registers	154
2.14.1.2	Machine Check Errors	155
2.14.1.3	Error Detection, Action, Logging, and Reporting	156
2.14.1.3.1	MCA conditions that cause Shutdown	157
2.14.1.3.2	Error Logging During Overflow	157
2.14.1.4	MCA Initialization	158
2.14.1.5	Error Code	158
2.14.1.6	Handling Machine Check Exceptions	160
2.14.1.6.1	Differentiation Between System-Fatal and Process-Fatal Errors	162
2.14.1.7	Error Thresholding	163
2.14.1.8	Scrub Rate Considerations	164
2.14.1.9	Error Diagnosis	165
2.14.1.9.1	Common Diagnosis Information	166
2.14.2	DRAM ECC Considerations	167
2.14.2.1	ECC Syndromes	167
2.14.2.1.1	x4 ECC	167
2.14.3	Error Injection and Simulation	169
2.14.3.1	DRAM Error Injection	169
2.15	Fusion Controller Hub	171
2.15.1	MMIO Programming for Legacy Devices	171
2.15.2	USB Controllers	171
2.15.2.1	USB Power Management	172
2.15.2.2	USB Interrupts	172
2.15.2.3	BIOS Programming Requirements For USB Reset During S3 Resume	172
2.15.2.4	Enabling the xHCI Controller	172
2.15.2.5	OHCI Arbiter Mode	172
2.15.2.6	USB2.0 Controller PHY Configuration and Calibration	173
2.15.2.7	USB2.0 Controller ISO Device CRC False Error Detection	173
2.15.2.8	xHC USB2.0 Common PHY Calibration	174
2.15.2.9	USB3.0 PHY Auto-Calibration Enablement	174
2.15.2.10	xHCI ISO Device CRC False Error Detection	174
2.15.2.11	xHCI PHY Clock Gating	175
2.15.2.12	xHCI Firmware Preload	175
2.15.2.13	xHCI Clear Pending PME on Sx State Entry	175
2.15.2.14	xHCI Enable OHCI3/EHCI3 on S4/S5 State Entry	176
2.15.3	SATA	176
2.15.3.1	SATA Operating Mode	176

2.15.3.2	SATA Drive Detection in IDE mode	176
2.15.3.3	SATA PHY Auto-Calibration Enablement	176
2.15.3.4	SATA PHY Fine Tuning	176
2.15.3.5	SATA PHY Reference Clock Selection	177
2.15.3.6	SATA Power Management	178
2.15.3.6.1	SATA PHY Power Saving	178
2.15.3.7	Enable Shadow Register Reload	178
2.15.3.8	SATA Interrupt Handling	178
2.15.3.8.1	Line Interrupt	178
2.15.3.8.2	MSI Message	178
2.15.3.9	Clear status of SATA PERR	179
2.15.4	LPC Bus Interface	179
2.15.4.1	Enabling LPC DMA function	179
2.15.4.2	Enabling SPI 100	179
2.15.5	SD Controller	179
2.15.6	HD Audio	179
2.15.6.1	HD Audio AF and MSI Capability	180
2.15.7	ASF Controller	180
2.15.8	Integrated Micro-Controller	180
2.15.9	On-Chip Clock Generator	180
2.15.9.1	Power Saving In Internal Clock Mode	181
2.15.9.2	Global A-Link / B-Link Clock Gating	181
2.15.9.3	CG_PLL CMOS Clock Driver Setting for Power Saving	181
2.15.10	Scallion Gasket	181
2.15.11	A-Link Bridge	181
2.15.11.1	Detection of Upstream Interrupts	181
2.15.11.2	AB Memory Power Saving	182
2.15.11.3	AB Internal Clock Gating	182
2.15.11.4	AB 32/64 Byte DMA Write Enable	182
3	Registers	183

Revision History

KB BKDG Revision 3.00 initial release.

1 Overview

This document defines AMD Family 16h Models 00h-0Fh Processors, henceforth referred to as the processor.

- The processor overview is located at [2.1 \[Processor Overview\]](#).
- The processor is distinguished by the combined ExtFamily and BaseFamily fields of the CPUID instruction (see [CPUID Fn8000_0001_EAX](#) in [3.18 \[CPUID Instruction Registers\]](#)).

1.1 Intended Audience

This document provides the processor behavioral definition and associated design notes. It is intended for platform designers and for programmers involved in the development of low-level BIOS (basic input/output system) functions, drivers, and operating system kernel modules. It assumes prior experience in personal computer platform design, microprocessor programming, and legacy x86 and AMD64 microprocessor architecture. The reader should also have familiarity with various platform technologies, such as DDR DRAM.

- Alert Standard Format Specification (<http://dmtf.org/standards/asf>)

1.3 Conventions

1.3.1 Numbering

- **Binary numbers.** Binary numbers are indicated by appending a “b” at the end, e.g., 0110b.
- **Decimal numbers.** Unless specified otherwise, all numbers are decimal. This rule does not apply to the register mnemonics described in [3.1 \[Register Descriptions and Mnemonics\]](#); register mnemonics all utilize hexadecimal numbering.
- **Hexadecimal numbers.** hexadecimal numbers are indicated by appending an “h” to the end, e.g., 45f8h.
- **Underscores in numbers.** Underscores are used to break up numbers to make them more readable. They do not imply any operation. E.g., 0110_1100b.

1.3.2 Arithmetic And Logical Operators

In this document, formulas generally follow Verilog conventions for logic equations.

Table 1: Arithmetic and Logical Operators

Operator	Definition
{}	Concatenation. Curly brackets are used to indicate a group of bits that are concatenated together. Each set of bits is separated by a comma. E.g., {Addr[3:2], Xlate[3:0]} represents a 6-bit value; the two MSBs are Addr[3:2] and the four LSB's are Xlate[3:0].
	Bitwise OR. E.g. (01b 10b == 11b).
	Logical OR. E.g. (01b 10b == 1b); treats multibit operand as 1 if >=1 and produces a 1-bit result.
&	Bitwise AND. E.g. (01b & 10b == 00b).
&&	Logical AND. E.g. (01b && 10b == 1b); logical treats multibit operand as 1 if >=1 and produces a 1-bit result.
^	Bitwise exclusive-OR. E.g. (01b ^ 10b == 11b). Sometimes used as “raised to the power of” as well, as indicated by the context in which it is used. E.g. (2^2 == 4).
~	Bitwise NOT. (also known as one's complement). E.g. (~10b == 01b).
!	Logical NOT. E.g. (!10b == 0b); treats multibit operand as 1 if >=1 and produces a 1-bit result.
<, <=, >, >=, ==, !=	Relational. Less than, Less than or equal, greater, greater than or equal, equal, and not equal.
+, -, *, /, %	Arithmetic. Addition, subtraction, multiplication, division, and modulus.
<<	Bitwise left shift. Shift left first operand by the number of bits specified by the 2nd operand. E.g. (01b << 01b == 10b).
>>	Bitwise right shift. Shift right first operand by the number of bits specified by the 2nd operand. E.g. (10b >> 01b == 01b).
?:	Ternary conditional. E.g. <i>condition ? value if true : value if false</i> . Equivalent to IF <i>condition</i> THEN <i>value if true</i> ELSE <i>value if false</i> .

Table 2: Functions

Function	Definition
ABS	ABS(integer-expression): Remove sign from signed value.
FLOOR	FLOOR(integer-expression): Rounds real number down to nearest integer.
CEIL	CEIL(real-expression): Rounds real number up to nearest integer.
MIN	MIN(integer-expression-list): Picks minimum integer or real value of comma separated list.
MAX	MAX(integer-expression-list): Picks maximum integer or real value of comma separated list.
COUNT	COUNT(integer-expression): Returns the number of binary 1's in the integer.

Table 2: Functions

Function	Definition
ROUND	ROUND(real-expression): Rounds to the nearest integer; halfway rounds away from zero.
UNIT	UNIT(fieldName UnitOfMeasure): Input operand is a register field name that defines all values with the same unit of measure. Returns the value expressed in the unit of measure for the current value of the register field.
POW	POW(base, exponent): POW(x,y) returns the value x to the power of y.

1.3.3 Operator Precedence and Associativity

This document follows C operator precedence and associativity. The following table lists operator precedence (highest to lowest). Their associativity indicates in what order operators of equal precedence in an expression are applied. Parentheses are also used to group sub-expressions to force a different precedence; such parenthetical expressions can be nested and are evaluated from inner to outer. E.g. “X = A | ~B & C” is the same as “X = A | ((~B) & C)”.

Table 3: Operator Precedence and Associativity

Operator	Description	Associativity
!, ~	Logical negation/bitwise complement	right-to-left
*, /, %	Multiplication/division/modulus	left-to-right
+, -	Addition/subtraction	left-to-right
<<, >>	Bitwise shift left, Bitwise shift right	left-to-right
<, <=, >, >=, ==, !=	Relational operators	left-to-right
&	Bitwise AND	left-to-right
^	Bitwise exclusive OR	left-to-right
	Bitwise inclusive OR	left-to-right
&&	Logical AND	left-to-right
	Logical OR	left-to-right
?:	Ternary conditional	right-to-left

1.4 Definitions

Table 4: Definitions

Term	Definition
AP	Application processor. See 2.3 [Processor Initialization] .
BAPM	Bidirectional Application Power Management. See 2.5.9.3 [Bidirectional Application Power Management (BAPM)] .
Battery-Power	The system is running from a battery power source or otherwise undocked from a continuous power supply. Setting using this definition may be required to change during runtime.
BCS	Base configuration space. See 2.7 [Configuration Space] .

Table 4: Definitions

Term	Definition
BERT	Bit error rate tester. A piece of test equipment that generates arbitrary test patterns and checks that a device under test returns them without errors.
BIST	Built-in self-test. Hardware within the processor that generates test patterns and verifies that they are stored correctly (in the case of memories) or received without error (in the case of links).
Boot VID	Boot voltage ID. This is the VDD and VDDNB voltage level that the processor requests from the external voltage regulator during the initial phase of the cold boot sequence. See 2.5.1.2 [Internal VID Registers and Encodings] .
BCD	Binary coded decimal number format.
BSC	Boot strap core. Core 0 of the BSP . Specified by MSR0000_001B[BSC] .
BSP	Boot strap processor. See 2.3 [Processor Initialization] .
CAR	Use of the L2 cache as RAM during boot. See 2.3.3 [Using L2 Cache as General Storage During Boot] .
C-states	These are ACPI-defined core power states. C0 is operational. All other C-states are low-power states in which the processor is not executing code. See 2.5.3.2 [Core C-states] .
Canonical address	An address in which the state of the most-significant implemented bit is duplicated in all the remaining higher-order bits, up to bit 63.
Channel	See DRAM channel.
CMP	Chip multi-processing. Refers to processors that include multiple cores. See 2.1 [Processor Overview] .
COF	Current operating frequency of a given clock domain. See 2.5.3 [CPU Power Management] .
Cold reset	PWROK is deasserted and RESET_L is asserted. See 2.3 [Processor Initialization] .
Core Cluster	Four JG Cores that share L2 resources. See L2 complex .
L2 complex	Four Cores that share L2 resources. See 2.1 [Processor Overview] .
Core	The instruction execution unit of the processor. See 2.1 [Processor Overview] .
CPB	Core performance boost. See 2.5.9.1 [Core Performance Boost (CPB)] .
CpuCore-Num	Specifies the core number. See 2.4.4 [Processor Cores and Downcoring] .
CPUID function X	Refers to the CPUID instruction when EAX is preloaded with X. See 3.18 [CPUID Instruction Registers] .
CS	Chip select. See D18F2x[5C:40]_dct[0] [DRAM CS Base Address] .
DCT	DRAM controller. See 2.9 [DRAM Controllers (DCTs)] .
DCQ	DRAM controller queue.
DDR3	DDR3 memory technology. See 2.9 [DRAM Controllers (DCTs)] .
DID	Divisor identifier. Specifies the post-PLL divisor used to reduce the COF. See 2.5.3 [CPU Power Management] .
Doubleword	A 32-bit value.
Downcoring	Removal of cores. See 2.4.4 [Processor Cores and Downcoring] .
DRAM channel	The part of the DRAM interface that connects to a DIMM. See 2.9 [DRAM Controllers (DCTs)] .

Table 4: Definitions

Term	Definition
Dual-Plane	Refers to a processor or systemboard where VDD and VDDNB are separate and may operate at independent voltage levels. Refer to 2.5.1 [Processor Power Planes And Voltage Control].
DW	Doubleword. A 32-bit value.
ECS	Extended configuration space. See 2.7 [Configuration Space].
EDS	Electrical data sheet. See 1.2 [Reference Documents].
FCH	Fusion Controller Hub. The integrated platform device that contains the IO subsystem and the bridge to system BIOS. See 2.15 [Fusion Controller Hub].
FDS	Functional data sheet; there is one FDS for each package type.
FID	Frequency identifier. Specifies the PLL frequency multiplier for a given clock domain. See 2.5.3 [CPU Power Management].
FreeR-unSample-Timer	An internal free running timer used by many power management features. The timer increments at the rate specified by D18F4x110[CSampleTimer].
GB	Gbyte or Gigabyte; 1,073,741,824 bytes.
#GP	A general-protection exception.
#GP(0)	Notation indicating a general-protection exception (#GP) with error code of 0.
GpuEnabled	GpuEnabled = (D1F0x00!=FFFF_FFFFh).
GT/s	Giga-transfers per second.
HCD	Host Controller Driver. A software component.
HTC	Hardware thermal control. See 2.10.3.1 [PROCHOT_L and Hardware Thermal Control (HTC)].
HTC-active state	Hardware-controlled lower-power, lower-performance state used to reduce temperature. See 2.10.3.1 [PROCHOT_L and Hardware Thermal Control (HTC)].
IBS	Instruction based sampling. See 2.6.2 [Instruction Based Sampling (IBS)].
IFCM	Isochronous flow-control mode, as defined in the link specification.
ILM	Internal loopback mode. Mode in which the link receive lanes are connected directly to the transmit lanes of the same link for testing and characterization. See D18F0x[18C:170] [Link Extended Control].
IO configuration	Access to configuration space through IO ports CF8h and CFCh. See 2.7 [Configuration Space].
IORR	IO range register. See MSRC001_00[18,16] [IO Range Base (IORR_BASE[1:0])].
KB	Kbyte or Kilobyte; 1024 bytes.
L1 cache	The level 1 caches (instruction cache and the data cache) and the level 2 caches. See 2.1 [Processor Overview].
L2 cache	
L2I	The L2 Interface complex common to a set of cores.
L2BC	L2I Base Core. The lowest numbered core for a L2I instance.
Linear (virtual) address	The address generated by a core after the segment is applied.
Link	Generic term that refers to a refer to PCIe® link.
LINT	Local interrupt.

Table 4: Definitions

Term	Definition
Logical address	The address generated by a core before the segment is applied.
LVT	Local vector table. A collection of APIC registers that define interrupts for local events. E.g., APIC[530:500] [Extended Interrupt [3:0] Local Vector Table] .
Master abort	This is a PCI-defined term that is applied to transactions on other than PCI buses. It indicates that the transaction is terminated without affecting the intended target; reads return all 1's; writes are discarded; the master abort error code is returned in the response, if applicable; master abort error bits are set if applicable.
MB	Megabyte; 1024 KB.
MCT	Memory controller. See 2.8 [Northbridge (NB)] .
MCQ	Memory controller queue. See 2.8 [Northbridge (NB)] .
Micro-op	Micro-op. Instructions have variable-length encoding and many perform multiple primitive operations. The processor does not execute these complex instructions directly, but, instead, decodes them internally into simpler fixed-length instructions called macro-ops. Processor schedulers subsequently break down macro-ops into sequences of even simpler instructions called micro-ops, each of which specifies a single primitive operation. See <i>Software Optimization Guide for AMD Family 16h Processors</i> .
MEMCLK	Refers to the clock signals, M[B, A][3:0]_CLK, that are driven from the processor to DDR DIMMs.
MMIO	Memory-mapped input-output range. This is physical address space that is mapped to the IO functions such as the IO links or MMIO configuration. The IO link MMIO ranges are specified by D18F1x[2CC:2A0,1CC:180,BC:80] [MMIO Base/Limit] .
MMIO configuration	Access to configuration space through memory space. See 2.7 [Configuration Space] .
MSR	Model-specific register. The core includes several MSRs for general configuration and control. See 3.19 [MSRs - MSR0000_xxxx] for the beginning of the MSR register definitions.
MTRR	Memory-type range register. The MTRRs specify the type of memory associated with various memory ranges. See MSR0000_00FE , MSR0000_020[F:0] , MSR0000_02[6F:68,59:58,50] , and MSR0000_02FF .
NB	Northbridge. The transaction routing block of the node. See 2.1 [Processor Overview] .
NBC	NBC = (CPUID Fn0000_0001_EBX[LocalApicId[3:0]]==0). Node Base Core. The lowest numbered core in the node.
NBPMC	Performance monitor counter. See 2.6.1.3 [NB Performance Monitor Counters] .
NCLK	The main northbridge clock. The NCLK frequency is the NB COF.
Node	See 2.1 [Processor Overview] .
Normalized address	Addresses used by DCTs. See 2.8 [Northbridge (NB)] .
OW	Octword. An 128-bit value.
ODM	On-DIMM mirroring. See D18F2x[5C:40]_dct[0][OnDimmMirror] .
ODT	On-die termination, which is applied DRAM interface signals.
ODTS	DRAM On-die thermal sensor.
Operational frequency	The frequency at which the processor operates. See 2.5 [Power Management] .

Table 4: Definitions

Term	Definition
PCIe®	PCI Express®.
PDS	Product data sheet.
Physical address	Addresses used by cores in transactions sent to the NB.
PMC	Performance monitor counter. See 2.6.1.1 [Core Performance Monitor Counters].
PRBS	Pseudo-random bit sequence.
Processor	See 2.1 [Processor Overview].
PSI	Power Status Indicator. See 2.5.1.3.1 [PSIx_L Bit].
P-state	Performance state. See 2.5 [Power Management].
PTE	Page table entry.
QW	Quadword. A 64-bit value.
RAS	Reliability, availability and serviceability (industry term). See 2.14.1 [Machine Check Architecture].
RDQ	Read data queue.
REFCLK	Reference Clock, refers to the clock frequency (100 MHz) or the clock period (10 ns) depending on the context used.
RX	Receiver.
RevA0	RevA0 = ((D18F3xFC[BaseModel] == 0h) && (D18F3xFC[Stepping] == 0h))
RevA1	RevA1 = ((D18F3xFC[BaseModel] == 0h) && (D18F3xFC[Stepping] == 1h)).
Scrubber	Background memory checking logic. See 2.8.3 [Memory Scrubbers].
Shutdown	A state in which the affected core waits for either INIT, RESET, or NMI. When shutdown state is entered, a shutdown special cycle is sent on the IO links.
Single-Plane	Refers to a processor or systemboard where VDD and VDDNB are tied together and operate at the same voltage level. Refer to 2.5.1 [Processor Power Planes And Voltage Control].
Slam	Refers to changing the voltage to a new value in one step (as opposed to stepping). See 2.5.1.4.1 [Hardware-Initiated Voltage Transitions].
SMAF	System management action field. This is the code passed from the SMC to the processors in STPCLK assertion messages. The action taken by the processors in response to this message is specified by D18F3x[84:80] [ACPI Power State Control].
SMBus	System management bus. Refers to the protocol on which the serial VID interface (SVI) commands are based. See 2.5.1 [Processor Power Planes And Voltage Control], and 1.2 [Reference Documents].
SMC	System management controller. This is the platform device that communicates system management state information to the processor through an IO link, typically the system IO hub.
SMI	System management interrupt. See 2.4.8.2.1 [SMM Overview].
SMM	System management mode. See 2.4.8.2 [System Management Mode (SMM)].
Speculative event	A performance monitor event counter that counts all occurrences of the event even if the event occurs during speculative code execution.
SVI2	Serial VID 2.0 interface. See 2.5.1.1 [Serial VID Interface]
SVM	Secure virtual machine. See 2.4.9 [Secure Virtual Machine Mode (SVM)].

Table 4: Definitions

Term	Definition
Sync flood	The propagation of continuous sync packets to all links. This is used to quickly stop the transmission of potentially bad data when there are no other means to do so. See the link specification for additional information.
TCC	Temperature calculation circuit. See 2.10 [Thermal Functions] .
Tctl	Processor temperature control value. See 2.10.3 [Temperature-Driven Logic] .
TDC	Thermal design current. See the AMD Infrastructure Roadmap, #41482.
TDP	Thermal design power. A power consumption parameter that is used in conjunction with thermal specifications to design appropriate cooling solutions for the processor. See 2.5.9.2 [TDP Limiting] .
Token	A scheduler entry used in various northbridge queues to track outstanding requests. See D18F3x140 [SRI to XCS Token Count] on Page 461.
TX	Transmitter.
UI	Unit interval. This is the amount of time equal to one half of a clock cycle.
UMI	Unified Media Interface. The link between the processor and the FCH.
VDD	Main power supply to the processor core logic.
VDDNB	Main power supply to the processor NB logic.
VID	Voltage level identifier. See 2.5.1 [Processor Power Planes And Voltage Control] .
Virtual CAS	The clock in which CAS is asserted for the burst, N, plus the burst length (in MEMCLKs), minus 1; so the last clock of virtual CAS = $N + (BL/2) - 1$.
VRM	Voltage regulator module.
W	Word. A 16-bit value.
Warm reset	RESET_L is asserted only (while PWROK stays high). See 2.3 [Processor Initialization] .
WDT	Watchdog timer. A timer that detects activity and triggers an error if a specified period of time expires without the activity. For example, see MSRC001_0074 [CPU Watchdog Timer (Cpu-WdtCfg)] or the NB watchdog timer in D18F3x40 [MCA NB Control] .
WDQ	Write data queue.
XBAR	Cross bar; command packet switch. See 2.8 [Northbridge (NB)] .

1.5 Changes Between Revisions and Product Variations

1.5.1 Revision Conventions

The processor revision is specified by [CPUID Fn0000_0001_EAX \[Family, Model, Stepping Identifiers\]](#) or [CPUID Fn8000_0001_EAX \[Family, Model, Stepping Identifiers\]](#). This document uses a revision letter instead of specific model numbers. The following table contains the definitions based on model and stepping used in this document. Where applicable, the processor stepping is indicated after the revision letter. All behavior marked with a revision letter apply to future revisions unless they are superseded by a change in a later revision. See the revision guide for additional information about revision determination. See [1.2 \[Reference Documents\]](#).

Table 5: Processor revision conventions

Term	Definition
PROC	Processor. PROC = {CPUID Fn0000_0001_EAX[ExtFamily], {CPUID Fn0000_0001_EAX[ExtModel], CPUID Fn0000_0001_EAX[BaseModel]}, CPUID Fn0000_0001_EAX[Stepping]}.
KB_A1	KB_A1 = {07h,00h,1h}.

1.5.2 Major Changes

This section describes the major changes relative to Family 14h Models 00h-0Fh (ON) Processors.

- CPU core (JG) changes, with respect to BT:
 - Architectural changes:
 - Shared L2 Cache.
 - MSRC001_023[6,4,2,0], MSRC001_023[7,5,3,1] L2I Performance counters indicated by CPUID Fn8000_0001_ECX[PerfCtrExtL2I].
 - MSRC001_024[6,4,2,0], MSRC001_024[7,5,3,1]: NB Performance counters indicated by CPUID Fn8000_0001_ECX[PerfCtrExtNB].
 - CPUID Fn8000_0008_EAX[PhysAddrSize]: Physical Address Extended to 40 bits.
 - CPUID Fn8000_0001_ECX[DataBreakpointExtension]: Debug Breakpoint Extension.
 - Instruction set changes:
 - CPUID Fn0000_0001_ECX[AVX]: Added AVX instruction support.
 - CPUID Fn0000_0001_ECX[XSAVE,OSXSAVE]: CPUID Fn0000_000D: Added XSAVE support.
 - CPUID Fn0000_0001_ECX[AES]: Added AES instruction support.
 - CPUID Fn0000_0001_ECX[SSE41, SSE42]: Added SSE4.1 and SSE4.2 instruction support.
 - CPUID Fn0000_0001_ECX[PCLMULQDQ]: Added PCLMULQDQ instruction support.
 - CPUID Fn0000_000D_EAX_x0-CPUID Fn0000_000D_EDX_x2: Added XSAVE/XRSTOR.
 - CPUID Fn0000_0001_ECX[MOVBE]: Added MOVBE instruction support.
 - CPUID Fn0000_0001_ECX[F16C]: Added F16C instruction support.
 - CPUID Fn0000_0007_EBX_x0[BMI1]: Added BMI1 instruction support.
 - Virtualization Support
 - CPUID Fn8000_000A_EDX[TscRateMsr]: Added TSC Scaling.
 - CPUID Fn8000_000A_EDX[FlushByAsid]: Added Flush by ASID.
 - CPUID Fn8000_000A_EDX[DecodeAssists]: Added Decode Assist.
 - CPUID Fn8000_000A_EDX[PauseFilterThreshold]: Added Enhanced Pause Filter.

1.5.2.1 Major Changes to Core/NB Performance Counters

Major Changes to Core/NB Performance Counters:

PerfMon Changes: Added L2I PerfMon group. See MSRC001_023[6,4,2,0] and MSRC001_023[7,5,3,1].

2 Functional Description

2.1 Processor Overview

The *processor* is defined as follows:

- The processor is a package that contains one node.
- Supports x86-based instruction sets.
- Packages:

- FT3: Notebook BGA Package.
- FS1b: Desktop uPGA Package.
- See [CUID Fn8000_0001_EBX\[PkgType\]](#).
- L2 complex

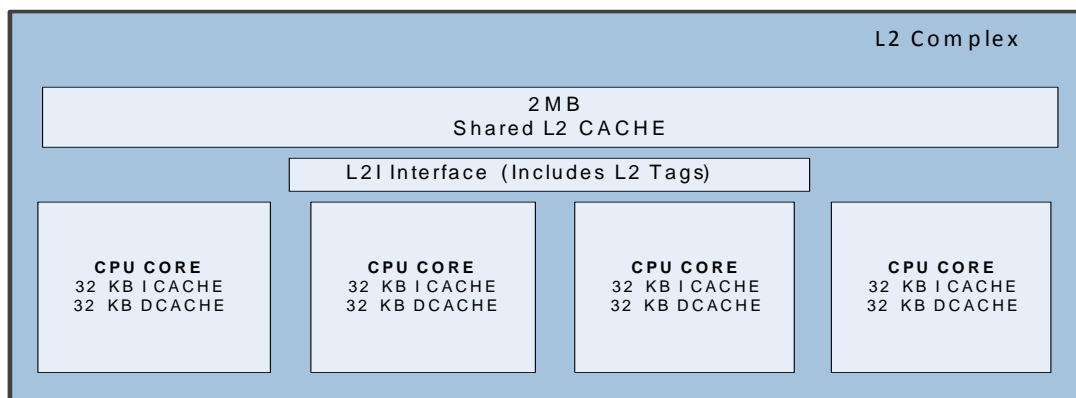

Figure 1: A L2 Complex

- 1 L2 complex (4 cores)
- 2 MB L2
- See [2.4.1 \[L2 complex\]](#).
- DRAM:
 - One 64-bit DDR3 memory channel (A). See [Figure 16 \[System Diagram\]](#).
- Northbridge (UNB):
 - One communication packet routing block referred to as the northbridge (NB). The NB routes transactions between the cores, the link, and the DRAM interfaces. It includes the configuration register space for the device.
- Graphics northbridge/GNB:
 - Link:
 - PCIe® Gen2
 - One x4 Gfx link, four x1 GPP links.
 - See [2.11.3 \[Links\]](#).
- Power Management:
 - See [2.5 \[Power Management\]](#).
- RAS:
 - See [2.14 \[RAS Features\]](#).

2.2 System Overview

2.3 Processor Initialization

This section describes the initialization sequence after a cold reset ([2.6.1 \[Cold Boot Sequence \(S4/S5 to S0\)\]](#)).

Core 0 of the processor, the bootstrap core (BSC), begins executing code from the reset vector. The remaining cores do not fetch code until their enable bits are set ([D18F0x1DC\[CpuEn\]](#)).

2.3.1 BSC Initialization

The BSC must perform the following tasks as part of boot.

- Store BIST information from the EAX register into an unused processor register.
- [D18F0x6C\[InitDet\]](#) may be used by BIOS to differentiate between INIT and cold/warm reset.
- Determine type of startup using [D18F0x6C\[ColdRstDet\]](#).
 - If this is a warm reset then BIOS may check for valid MCA errors and if present save the status for later use. See [2.14.1.6 \[Handling Machine Check Exceptions\]](#).
- Enable the cache, program the MTRRs for [CAR](#) and initialize [CAR](#). See [2.3.3 \[Using L2 Cache as General Storage During Boot\]](#).
- Setup the SMU (BOZO: SMU init section).
- Setup of APIC ([2.4.8.1.3 \[ApicId Enumeration Requirements\]](#)).
- Setup the link configuration [2.11.3.2 \[Link Configurations\]](#).
- Setup the root complex and initialize the I/O links [2.11.4.3 \[Link Configuration and Initialization\]](#).
- If required, reallocate data and flow control buffers of the links (see [D18F0x\[F0,D0,B0,90\] \[Link Base Channel Buffer Count\]](#) and [D18F0x\[F4,D4,B4,94\] \[Link Isochronous Channel Buffer Count\]](#)).
- Issue system warm reset. See [2.6.2 \[Warm Reset Sequence\]](#).
- Configure the DRAM controllers.
- Configure processor power management. See [2.5 \[Power Management\]](#).
- Allow other cores to begin fetching instructions by setting [D18F0x1DC\[CpuEn\]](#) in the PCI configuration space of all nodes. See [2.4.4 \[Processor Cores and Downcoring\]](#).

2.3.2 AP Initialization

All other processor cores other than core 0 begin executing code from the reset vector. They must perform the following tasks as part of boot.

- Store BIST information from the eax register into an unused processor register.
- [D18F0x6C\[InitDet\]](#) may be used by BIOS to differentiate between INIT and cold/warm reset.
- Determine the history of this reset using the [D18F0x6C \[Link Initialization Control\] \[ColdRstDet\]](#) bit:
 - If this is a warm reset then BIOS may check for valid MCA errors and if present save the status for use later. See [2.14.1.6 \[Handling Machine Check Exceptions\]](#).
- Set up the local APIC. See [2.4.8.1.3 \[ApicId Enumeration Requirements\]](#).
- Configure processor power management. See [2.4 \[Core\]](#).

2.3.3 Using L2 Cache as General Storage During Boot

Prior to initializing the DRAM controller for system memory, BIOS may use the L2 cache as general storage. If BIOS is not using L2 cache as general storage during boot, program [MSRC001_102A\[CILinesToL2Dis\]](#)=0.

The L2 cache as general storage is described as follows:

- Each L2 complex has its own L2 cache.
- BIOS manages the mapping of the L2 storage such that cacheable accesses do not cause L2 victims.
- The L2 size, L2 associativity, and L2 line size is determined by reading [CPUID Fn8000_0006_ECX\[L2Size, L2Assoc, L2LineSize\]](#). L2WayNum is defined to be the number of ways indicated by the L2Assoc code.
 - The L2 cache is viewed as (L2Size/L2LineSize) cache lines of storage, organized as L2WayNum ways, each way being (L2Size/L2WayNum) in size.
 - E.g. L2Assoc=8 so L2WayNum=16 (there are 16 ways). If (L2Size=2MB) then there are 16 blocks of cache, each 2MB/16 in size, or 128KB each.

- For each of the following values of L2Size, the following values are defined:
 - L2Size=1 MB: L2Tag=PhysAddr[39:16], L2WayIndex=PhysAddr[15:6].
 - L2Size=2 MB: L2Tag=PhysAddr[39:17], L2WayIndex=PhysAddr[16:6].
- PhysAddr[5:0] addresses the L2LineSize number of bytes of storage associated with the cache line.
- The L2 cache, when allocating a line at L2WayIndex:
 - Picks an invalid way before picking a valid way.
 - Prioritizes the picking of invalid ways such that way 0 is the highest priority and L2WayNum-1 is the lowest priority.
- It is recommended that BIOS assume a simpler allocation of L2 cache memory, being L2WayNum size-aligned blocks of memory, each being L2Size/L2WayNum bytes.
- BIOS can rely on a minimum L2Size of 1 MB and can rely on being able to use all 16 ways for general storage. See [CUID Fn8000_0006_ECX\[L2Size\]](#).

The following memory types are supported:

- WP-IO: BIOS ROM may be assigned the write-protect IO memory type and may be accessed read-only as data and fetched as instructions.
 - WP-IO accesses, both read and write, do not get allocated into the L2 and therefore do not need to be considered for allocation into the L2.
- WB-DRAM: General storage may be assigned the write-back DRAM memory type and may be accessed as read-write data, but not accessed by instruction fetch.
 - BIOS initializes an L2LineSize sized and aligned location in the L2 cache, mapped as write-back DRAM, with 1 read to at least 1 byte of the L2LineSize sized and aligned WB-DRAM address. BIOS may store to a line only after it has been allocated by a load.
 - Fills, sent to the disabled memory controller, return undefined data.
- All of memory space that is not accessed as WP-IO or WB-DRAM space must be marked as UC memory type.
- In order to prevent victimizing L2 data, no more than L2WayNum cache lines accessed as WB-DRAM may have the same L2WayIndex.
 - Software does not need to know which ways the L2WayNum lines are allocated to for any given value of L2WayIndex, only that invalid ways will be selected for allocation before valid ways will be selected for allocation.
 - Software is not allowed to deallocate a line in the L2 by using CLFLUSH.

Performance monitor event [L2IPMCx060\[3:2\]](#), titled “write victim block”, can be used to indicate whether L2 dirty data was lost by being victimized and sent to the disabled memory controller.

The following requirements must be satisfied prior to using the cache as general storage:

- Paging must be disabled. Reason: The caching of TLB entries will displace L2 cache entries.
- [MSRC001_0015\[INVDWBINVD\]](#)=0. Reason: INVD's must be prevented from pushing dirty data to uninitialized DRAM.
- [MSRC001_1021\[DisSpecTlbRld\]](#)=1. Disable speculative ITLB reloads. Reason: Prevent misinterpreted speculative IFetch from accessing WB-DRAM dirty lines as code and evicting them from the L2.
- [MSRC001_1022\[DisSpecTlbWalk\]](#)=1. Disable speculative DTLB reloads. Reason: BIOS has been known to map more memory as WB-DRAM than the size of the L2. Setting this bit will prevent mispredicted speculative data accesses from accessing a region outside of the [CAR](#) region that may be mapped as WB-DRAM and cause an L2 eviction.
- [MSRC001_1022\[DisHwPf\]](#)=1.
- [MSRC001_10A0\[L2RinserDis\]](#)=1. Reason: Disable background removal of stored data.
- [MSRC001_10A0\[PrefetcherDis\]](#)=1. Disable L2 hardware prefetcher.
- [MSRC001_10A0\[CacheIcAttrDis\]](#)=1. Reason: If there is data access to an instruction line whose attri-

butes were written into that the L2 cache, we would get an L2 eviction so the line could be reloaded from the NB with ECC.

- CLFLUSH, INVD, and WBINVD must not be used during **CAR** but may be used when tearing down **CAR** for all compute units on a node. Reason: In order to ensure that data L2 data for a compute unit is not evicted when another compute unit completes use of **CAR**.
- The BIOS must not use SSE, or MMX™ instructions, with the exception of the following list: MOVD, MOVQ, MOVDQA, MOVQ2DQ, MOVDQ2Q.
- The BIOS must not enable exceptions, page-faults, and other interrupts.
- BIOS must not use software prefetches.
- UC-DRAM: All of DRAM that is not accessed as WB-DRAM space must be marked as UC memory type. Reason: This prevents speculative accesses that fall outside of the **CAR** region from getting to the caches and DRAM controller.

When BIOS has completed using the cache for general storage the following steps are followed:

1. Prior to issuing an INVD instruction, BIOS must ensure that no other source of coherent traffic, such as a DMA engine, is operating in the system. This condition must hold true until the INVD instruction for tear-down has been executed on all CPUs.
2. An INVD instruction is executed on each core that used cache as general storage; an INVD is issued when all cores on all nodes have completed using the cache for general storage.
3. If DRAM is initialized and there is data in the cache that needs to get moved to main memory, CLFLUSH or WBINVD may be used instead of INVD, but software must ensure that needed data in main memory is not overwritten.
4. Program the following configuration state (Order is unimportant):
 - **MSRC001_0015**[INVDWBINVD]=1.
 - **MSRC001_1021**[DisSpecTlbRld]=0.
 - **MSRC001_1022**[DisSpecTlbWalk]=0.
 - **MSRC001_1022**[DisHwPf]=0.
 - **MSRC001_10A0**[PrefetcherDis]=0.
 - **MSRC001_10A0**[CacheIcAttrDis]=0.
 - **MSRC001_102A**[CilinesToL2Dis]=0.

2.3.4 Instruction Cache Configuration Register Usage Requirements

Modification of **MSRC001_1021** [Instruction Cache Configuration (IC_CFG)] requires the following steps for all cores within the L2 complex:

- Synchronize all cores.
- Modify **MSRC001_1021** observing the **Same-for-all** requirement.
- Flush all caches using WBINVD for all cores within the L2 complex.
- Resume all cores.

2.4 Core

The majority of the behavioral definition of the core is specified in the AMD64 Architecture Programmer's Manual. See 1.2 [Reference Documents].

2.4.1 L2 complex

Each *L2 complex* or cluster includes 4 cores each having an x86 instruction execution logic and first-level (L1) data cache and first-level (L1) instruction cache. The second level (L2) general-purpose cache is shared between all cores of the L2 complex.

There is a set of MSRs and APIC registers associated with each core. Processors that include multiple cores are

said to incorporate *chip multi-processing* or CMP. Unless otherwise specified the processor configuration interface hides the L2 complex implementation and presents software with homogenous cores, each independent of the other.

Software may use [D18F5x80](#)[Enabled, DualCore, TripleCore, QuadCore] in order to associate a core with a L2 complex. This information can be useful because some configuration settings are determined based on active L2 complexes and core performance may vary based on resource sharing within a L2 complex.

2.4.2 Caches and TLBs

Cache and TLB storage available to a core is reported by:

- [CPUID Fn8000_0005_EAX](#)-[CPUID Fn8000_0006_EDX](#).
- [CPUID Fn8000_0019_EAX](#)-[CPUID Fn8000_0019_E\[D,C\]X](#).
- [CPUID Fn8000_001D_EAX_x0](#)-[CPUID Fn8000_001E_EDX](#).

Cache and TLB storage available to a core is summarized as follows:

- L1 and L2 Caches:
 - DC: 32 KB, 8-way, write-back, per-core.
 - IC: 32 KB, 2-way, per-core.
 - L2: 1 MB or 2 MB (Product-specific), 16-way associative, shared between all cores of a L2 complex.
- TLBs:
 - D, L1TLB:
 - 4 KB: 40 entries, fully associative.
 - 2 MB: 8 entries, fully associative.
 - D, L2TLB:
 - 4 KB: 512 entries, 4 way associative
 - 2 MB: 256 entries, hashed 2 way associative.
 - I, L1TLB:
 - 4 KB: 32 entries, fully associative.
 - 2 MB, 8 entries, fully associative.
 - I, L2TLB:
 - 4 KB: 512 entries, 4-way associative.

2.4.2.1 Registers Shared by Cores in a L2 complex

Some registers are implemented one instance per L2 complex instead of per core; these registers are designated as [Per-L2](#). The absence of [Per-L2](#) implies the normal per-core instance programming model.

Programming rules for [Per-L2](#) registers:

- Software must ensure that a shared MSR written by one core on a L2 complex will not cause a problem for software that is running on the other core of the L2 complex.
- [Per-L2](#): A write to a [Per-L2](#) MSR does not have to be written to the other cores of the L2 complex in order for the other cores to see the updated value.
- A read-modify-write of a shared MSR register is not atomic. Software must ensure atomicity between the cores that could simultaneously read-modify-write the shared register.

2.4.3 Virtual Address Space

The processor supports 48 address bits of virtual memory space (256 TB) as indicated by [CPUID Fn8000_0008_EAX](#).

2.4.4 Processor Cores and Downcoring

Each L2 Complex supports downcoring as follows:

- The number of fuse enabled cores supported is specified by [D18F5x84\[CmpCap\]](#).
- The cores of a L2 complex may be software downcored by [D18F3x190\[DisCore\]](#). See 2.4.4.1 [Software Downcoring using [D18F3x190\[DisCore\]](#)].
 - Clocks are turned off and power is gated to software or fuse downcored L2 complexes. The power savings is the same as CC6.
 - There must be at least 1 L2 complex enabled.
 - [D18F3x190\[DisCore\]](#) affects the value of [CPUID Fn0000_0001_EBX\[LogicalProcessorCount\]](#), [CPUID Fn0000_0001_EDX\[HTT\]](#), [CPUID Fn8000_0001_ECX\[CmpLegacy\]](#), [CPUID Fn8000_0008_ECX\[NC\]](#), [D18F3x12C\[CpuNum\]](#), [D18F5x80\[Enabled, DualCore, TripleCore, Quad-Core\]](#). [D18F3x190\[DisCore\]](#) does not affect the value of [D18F5x84\[CmpCap\]](#).
- An implemented (physical) core that is downcored is not visible to software. Cores that are not downcored are numbered logically in a contiguous manner. The physical to logical mapping is described as follows:
- [D18F5x80 \[Compute Unit Status 1\]](#) reports core topology information to software.
- The number of cores specified in [CPUID Fn8000_0008_ECX\[NC\]](#) must be the same as the number of cores enabled in [D18F0x1DC\[CpuEn\]](#).
- The core number, *CpuCoreNum*, is provided to SW running on each core through [CPUID Fn0000_0001_EBX\[LocalApicId\]](#) and [APIC20\[ApicId\]](#); *CpuCoreNum* also affects [D18F0x1DC\[CpuEn\]](#). *CpuCoreNum*, varies as the lowest integers from 0 to [D18F5x84\[CmpCap\]](#), based on the number of enabled cores; e.g., a 4-core node with 1 core disabled results in cores reporting *CpuCoreNum* values of 0, 1, and 2 regardless of which core is disabled. The boot core is always the core reporting *CpuCoreNum*=0.

Some legacy operating systems do not support processors with a non-power-of-2 number of cores. The BIOS is recommended to support a user configurable option to disable cores down to a power-of-2 number of cores for legacy operating system support.

2.4.4.1 Software Downcoring using [D18F3x190\[DisCore\]](#)

Cores may be downcored by [D18F3x190\[DisCore\]](#).

Software is required to use [D18F3x190\[DisCore\]](#) as follows:

- Setting bits corresponding to cores that are not present results in undefined behavior.
- Once a core has been removed by [D18F3x190\[DisCore\]=1](#), it cannot be added back without a cold reset. E.g. Software may only set *DisCore* bits, never clear them.
- For enabled L2 complexes where (*L2 complex* ≥ 1) software may not disable logical Core 0 of the L2 complex.
- The most significant bit N, affected by *Fuse[CoreDis]*, is (the number of cores)-1 at cold reset; the number of cores at cold reset is ([CPUID Fn8000_0008_ECX\[NC\]](#)+1).
- The most significant bit N and the logical core ID significance of *DisCore* is not affected by the value of *DisCore* followed by a warm-reset.
 - E.g. If logical core 2 is disabled by *DisCore*[3:0]=0100b followed by a warm reset, then the new logical core 2 is the old logical core 3. If the new logical core 2 needs to then be disabled then *DisCore*[3:0]=1100b followed by a warm reset.
- All bits greater than bit N are reserved. Bits greater than N associated with a fuse disabled core are read-write. Bits greater than N associated with a non-existent core are read-only.
- If [D18F3x190\[DisCore\]](#) is changed, then the following need to be updated:
 - [D18F0x60\[CpuCnt\[4:0\]\]](#).
 - [D18F5x170\[NbPstateThreshold\]](#)

2.4.5 Physical Address Space

The processor supports a 40 bit physical address space, as indicated by [CPUID Fn8000_0008_EAX \[Long Mode Address Size Identifiers\]](#).

The processor master aborts the following upper-address transactions (to address PhysAddr):

- Link or core requests with non-zero PhysAddr[63:40].

2.4.6 System Address Map

The processor defines a reserved memory address region starting at 0000_00FD_0000_0000h and extending up to 0000_0100_0000_0000h. System software must not map memory into this region. Downstream host accesses to the reserved address region results in a page fault. Upstream system device accesses to the reserved address region results in an undefined operation.

2.4.6.1 Memory Access to the Physical Address Space

All memory accesses to the physical address space from a core are sent to its associated northbridge (NB). All memory accesses from a link are routed through the NB. An IO link access to physical address space indicates to the NB the cache attribute (Coherent or Non-coherent, based on bit[0] of the Sized Read and Write commands).

A core access to physical address space has two important attributes that must be determined before issuing the access to the NB: the memory type (e.g., WB, WC, UC; as described in the MTRRs) and the access destination (DRAM or MMIO).

This mechanism is managed by the BIOS and does not require any setup or changes by system software.

2.4.6.1.1 Determining Memory Type

The memory type for a core access is determined by the highest priority of the following ranges that the access falls in: 1==Lowest priority.

1. The memory type as determined by architectural mechanisms.
 - See the APM2 chapter titled “Memory System”, sections “Memory-Type Range Registers” and “Page-Attribute Table Mechanism”.
 - See the APM2 chapter titled “Nested Paging”, section “Combining Memory Types, MTRRs”.
 - See [MSR0000_02FF \[MTRR Default Memory Type \(MTRRdefType\)\]](#), [MSR0000_020\[F:0\] \[Variable-Size MTRRs Base/Mask\]](#), [MSR0000_02\[6F:68,59:58,50\] \[Fixed-Size MTRRs\]](#).
2. TSeg & ASeg SMM mechanism. (see [MSRC001_0112](#) and [MSRC001_0113](#))
3. CR0[CD]: If (CR0[CD]==1) then MemType=CD.
4. MMIO config space, APIC space.
 - MMIO APIC space and MMIO config space must not overlap.
 - MemType=UC.
 - See [2.4.8.1.2 \[APIC Register Space\]](#) and [2.7 \[Configuration Space\]](#).
5. SmmATValNoMchFrcCD: If (“In SMM Mode” && ([MSRC001_102A](#)[SmmATValNoMchFrcCD-Dis]==0) && ~(([MSRC001_0113](#)[AValid] && “The address falls within the ASeg region”) || ([MSRC001_0113](#)[TValid] && “The address falls within the TSeg region”))) then MemType=CD.

2.4.6.1.2 Determining The Access Destination for Core Accesses

The access destination, DRAM or MMIO, is based on the highest priority of the following ranges that the access falls in: 1==Lowest priority.

1. RdDram/WrDram as determined by [MSRC001_001A \[Top Of Memory \(TOP_MEM\)\]](#) and [MSRC001_001D \[Top Of Memory 2 \(TOM2\)\]](#).
2. The IORRs. (see [MSRC001_00\[18,16\]](#) and [MSRC001_00\[19,17\]](#)).
3. The fixed MTRRs. (see [MSR0000_02\[6F:68,59:58,50\] \[Fixed-Size MTRRs\]](#))
4. TSeg & ASeg SMM mechanism. (see [MSRC001_0112](#) and [MSRC001_0113](#))
5. MMIO config space, APIC space.
 - MMIO APIC space and MMIO config space must not overlap.
 - RdDram=IO, WrDram=IO.
 - See [2.4.8.1.2 \[APIC Register Space\]](#) and [2.7 \[Configuration Space\]](#).
6. NB address space routing. See [2.8.2.1.1 \[DRAM and MMIO Memory Space\]](#).

2.4.7 Timers

Each core includes the following timers. These timers do not vary in frequency regardless of the current P-state or C-state.

- [MSR0000_0010 \[Time Stamp Counter \(TSC\)\]](#); the TSC increments at the rate specified by the P0 P-state.
 - See [2.5.3.1.1.1 \[Software P-state Numbering\]](#).
 - See [MSRC001_00\[6B:64\] \[P-state \[7:0\]\]](#).
- The APIC timer ([APIC380](#) and [APIC390](#)), which increments at the rate of 2xCLKIN; the APIC timer may increment in units of between 1 and 8.

2.4.8 Interrupts

2.4.8.1 Local APIC

The local APIC contains logic to receive interrupts from a variety of sources and to send interrupts to other local APICs, as well as registers to control its behavior and report status. Interrupts can be received from:

- IO devices including the IO hub (IO APICs)
- Other local APICs (inter-processor interrupts)
- APIC timer
- Thermal events
- Performance counters
- Legacy local interrupts from the IO hub (INTR and NMI)
- APIC internal errors

The APIC timer, thermal events, performance counters, local interrupts, and internal errors are all considered local interrupt sources, and their routing is controlled by local vector table entries. These entries assign a message type and vector to each interrupt, allow them to be masked, and track the status of the interrupt.

IO and inter-processor interrupts have their message type and vector assigned at the source and are unaltered by the local APIC. They carry a destination field and a mode bit that together determine which local APIC(s) accepts them. The destination mode (DM) bit specifies if the interrupt request packet should be handled in physical or logical destination mode. If the destination field matches the broadcast value specified by [D18F0x68\[ApicExtBrdCst\]](#), then the interrupt is a broadcast interrupt and is accepted by all local APICs regardless of destination mode.

2.4.8.1.1 Detecting and Enabling

APIC is detected and enabled via [CPUID Fn0000_0001_EDX\[APIC\]](#).

The local APIC is enabled via [MSR0000_001B](#)[ApicEn]. Reset forces APIC disabled.

2.4.8.1.2 APIC Register Space

MMIO APIC space:

- Memory mapped to a 4 KB range. The memory type of this space is the UC memory type; also, hardware forces the 4 KB page mapped by ApicBar to UC. The base address of this range is specified by {[MSR0000_001B](#)[ApicBar[47:12]], 000h}.
- The mnemonic is defined to be APICXX; XX is the byte address offset from the base address.
- MMIO APIC registers in xAPIC mode is defined by the register from [APIC20](#) to [APIC\[530:500\]](#).
- Treated as normal memory space when APIC is disabled, as specified by [MSR0000_001B](#)[ApicEn].

2.4.8.1.3 ApicId Enumeration Requirements

System hardware and BIOS must ensure that the number of cores per processor (NC) exposed to the operating system by all tables, registers, and instructions across all cores in the processor is identical. See [2.4.10.1 \[Multi-Core Support\]](#) to derive NC.

Operating systems are expected to use [CPUID Fn8000_0008_ECX](#)[ApicIdCoreIdSize], the number of least significant bits in the Initial APIC ID that indicate core ID within a processor, in constructing per-core CPUID masks. (ApicIdCoreIdSize[3:0] determines the maximum number of cores (MNC) that the processor could theoretically support, not the actual number of cores that are actually implemented or enabled on the processor, as indicated by [CPUID Fn8000_0008_ECX](#)[NC].) $MNC = (2^{CPUID\ Fn8000_0008_ECX[ApicIdCoreIdSize]})$. BIOS must use the ApicId MNC rule when assigning [APIC20](#)[ApicId] values as described below.

ApicId MNC rule: The ApicId of core j on processor i must be enumerated/assigned as:

- $ApicId[proc=i, core=j] = (OFFSET_IDX + i) * MNC + j$
- Where OFFSET_IDX is an integer offset (0 to N) used to shift up the core ApicId values to allow room for IOAPIC devices.

It is recommended that BIOS use the following APIC ID assignments for the broadest operating system support. Given $N = (Number_Of_Processors * MNC)$ and $M = Number_Of_IOAPICs$:

- If $(N+M) < 16$, then assign the local (core) ApicIds first from 0 to N-1, and the IOAPIC IDs from N to N+(M-1). APIC ID 15 is reserved for broadcast when [APIC410](#)[ExtApicIdEn]==0.
- If $(N+M) \geq 16$, then assign the IOAPIC IDs first from 0 to M-1, and the local (core) ApicIds from K to K+(N-1), where K is an integer multiple of MNC greater than M-1.

2.4.8.1.4 Physical Destination Mode

The interrupt is only accepted by the local APIC whose [APIC20](#)[ApicId] matches the destination field of the interrupt. Physical mode allows up to 255 APICs to be addressed individually.

2.4.8.1.5 Logical Destination Mode

A local APIC accepts interrupts selected by [APICD0](#) [Logical Destination (LDR)] and the destination field of the interrupt using either cluster or flat format as configured by [APICE0](#)[Format].

If flat destinations are in use, bits 7-0 of [APICD0](#)[Destination] are checked against bits 7-0 of the arriving interrupt's destination field. If any bit position is set in both fields, the local APIC is a valid destination. Flat format allows up to 8 APICs to be addressed individually.

If cluster destinations are in use, bits 7-4 of [APICD0](#)[Destination] are checked against bits 7-4 of the arriving

interrupt's destination field to identify the cluster. If all of bits 7-4 match, then bits 3-0 of [APICD0\[Destination\]](#) and the interrupt destination are checked for any bit positions that are set in both fields to identify processors within the cluster. If both conditions are met, the local APIC is a valid destination. Cluster format allows 15 clusters of 4 APICs each to be addressed.

2.4.8.1.6 Interrupt Delivery

SMI, NMI, INIT, Startup, and External interrupts are classified as non-vectorized interrupts.

When an APIC accepts a non-vectorized interrupt, it is handled directly by the processor instead of being queued in the APIC. When an APIC accepts a fixed or lowest-priority interrupt, it sets the bit in [APIC\[270:200\] \[Interrupt Request \(IRR\)\]](#) corresponding to the vector in the interrupt. For local interrupt sources, this comes from the vector field in that interrupt's local vector table entry. The corresponding bit in [APIC\[1F0:180\] \[Trigger Mode \(TMR\)\]](#) is set if the interrupt is level-triggered and cleared if edge-triggered. If a subsequent interrupt with the same vector arrives when the corresponding bit in [APIC\[270:200\]\[RequestBits\]](#) is already set, the two interrupts are collapsed into one. Vectors 15-0 are reserved.

2.4.8.1.7 Vectored Interrupt Handling

[APIC80 \[Task Priority \(TPR\)\]](#) and [APICA0 \[Processor Priority \(PPR\)\]](#) each contain an 8-bit priority divided into a main priority (bits 7-4) and a priority sub-class (bits 3-0). The task priority is assigned by software to set a threshold priority at which the processor is interrupted.

The processor priority is calculated by comparing the main priority (bits 7-4) of [APIC80\[Priority\]](#) to bits 7-4 of the 8-bit encoded value of the highest bit set in [APIC\[170:100\] \[In-Service \(ISR\)\]](#). The processor priority is the higher of the two main priorities.

The processor priority is used to determine if any accepted interrupts (indicated by [APIC\[270:200\]\[Request-Bits\]](#)) are high enough priority to be serviced by the processor. When the processor is ready to service an interrupt, the highest bit in [APIC\[270:200\]\[RequestBits\]](#) is cleared, and the corresponding bit is set in [APIC\[170:100\]\[InServiceBits\]](#).

When the processor has completed service for an interrupt, it performs a write to [APICB0 \[End of Interrupt\]](#), clearing the highest bit in [APIC\[170:100\]\[InServiceBits\]](#) and causing the next-highest interrupt to be serviced. If the corresponding bit in [APIC\[1F0:180\]\[TriggerModeBits\]](#) is set, a write to [APICB0](#) is performed on all APICs to complete service of the interrupt at the source.

2.4.8.1.8 Interrupt Masking

Interrupt masking is controlled by the [APIC410 \[Extended APIC Control\]](#). If [APIC410\[IerEn\]](#) is set, [APIC\[4F0:480\] \[Interrupt Enable\]](#) are used to mask interrupts. Any bit in [APIC\[4F0:480\]\[InterruptEnableBits\]](#) that is clear indicates the corresponding interrupt is masked. A masked interrupt is not serviced and the corresponding bit in [APIC\[270:200\]\[RequestBits\]](#) remains set.

2.4.8.1.9 Spurious Interrupts

In the event that the task priority is set to or above the level of the interrupt to be serviced, the local APIC delivers a spurious interrupt vector to the processor, as specified by [APICF0 \[Spurious-Interrupt Vector \(SVR\)\]](#). [APIC\[170:100\]](#) is not changed and no write to [APICB0](#) occurs.

2.4.8.1.10 Spurious Interrupts Caused by Timer Tick Interrupt

A typical interrupt is asserted until it is serviced. An interrupt is deasserted when software clears the interrupt status bit within the interrupt service routine. Timer tick interrupt is an exception, since it is deasserted regardless of whether it is serviced or not.

The processor is not always able to service interrupts immediately (i.e. when interrupts are masked by clearing EFLAGS.IM or when the processor is in PDM).

If the processor is not able to service the timer tick interrupt for an extended period of time, the INTR caused by the first timer tick interrupt asserted during that time is delivered to the local APIC in ExtInt mode and latched, and the subsequent timer tick interrupts are lost. The following cases are possible when the processor is ready to service interrupts:

- An ExtInt interrupt is pending, and INTR is asserted. This results in timer tick interrupt servicing. This occurs 50 percent of the time.
- An ExtInt interrupt is pending, and INTR is deasserted. The processor sends the interrupt acknowledge cycle, but when the PIC receives it, INTR is deasserted, and the PIC sends a spurious interrupt vector. This occurs 50 percent of the time.

There is a 50 percent probability of spurious interrupts to the processor.

2.4.8.1.11 Lowest-Priority Interrupt Arbitration

Fixed, remote read, and non-vectored interrupts are accepted by their destination APICs without arbitration.

Delivery of lowest-priority interrupts requires all APICs to arbitrate to determine which one accepts the interrupt. If [APICF0\[FocusDisable\]](#) is clear, then the focus processor for an interrupt always accepts the interrupt. A processor is the focus of an interrupt if it is already servicing that interrupt (corresponding bit in [APIC\[170:100\]\[InServiceBits\]](#) is set) or if it already has a pending request for that interrupt (corresponding bit in [APIC\[270:200\]\[RequestBits\]](#) is set). If [APIC410\[IerEn\]](#) is set the interrupt must also be enabled in [APIC\[4F0:480\]\[InterruptEnableBits\]](#) for a processor to be the focus processor. If there is no focus processor for an interrupt, or focus processor checking is disabled, then each APIC calculates an arbitration priority value, stored in [APIC90 \[Arbitration Priority \(APR\)\]](#), and the one with the lowest result accepts the interrupt.

The arbitration priority value is calculated by comparing [APIC80\[Priority\]](#) with the 8-bit encoded value of the highest bit set in [APIC\[270:200\]\[RequestBits\]](#) (IRRVec) and the 8-bit encoded value of the highest bit set in [APIC\[170:100\]\[InServiceBits\]](#) (ISRVec). If [APIC410\[IerEn\]](#) is set the IRRVec and ISRVec are based off the highest enabled interrupt. The main priority bits 7-4 are compared as follows:

```
IF ((APIC80[Priority[7:4]] >= IRRVec[7:4]) && (APIC80[Priority[7:4]] > ISRVec[7:4])) THEN
    APIC90[Priority] = APIC80[Priority]
ELSEIF (IRRVec[7:4] > ISRVec[7:4]) THEN
    APIC90[Priority] = {IRRVec[7:4],0h}
ELSE
    APIC90[Priority] = {ISRVec[7:4],0h}
ENDIF.
```

2.4.8.1.12 Inter-Processor Interrupts

[APIC300 \[Interrupt Command Low \(ICR Low\)\]](#) and [APIC310 \[Interrupt Command High \(ICR High\)\]](#) provide a mechanism for generating interrupts in order to redirect an interrupt to another processor, originate an interrupt to another processor, or allow a processor to interrupt itself. A write to register [APIC300](#) causes an inter-

rupt to be generated with the properties specified by the [APIC300](#) and [APIC310](#) fields.

2.4.8.1.13 APIC Timer Operation

The local APIC contains a 32-bit timer, controlled by [APIC320 \[LVT Timer\]](#), [APIC380 \[Timer Initial Count\]](#), and [APIC3E0 \[Timer Divide Configuration\]](#). The processor bus clock is divided by the value in [APIC3E0\[Div\]](#) to obtain a time base for the timer. When [APIC380\[Count\]](#) is written, the value is copied into [APIC390 \[Timer Current Count\]](#). [APIC390\[Count\]](#) is decremented at the rate of the divided clock. When the count reaches 0, a timer interrupt is generated with the vector specified in [APIC320\[Vector\]](#). If [APIC320\[Mode\]](#) specifies periodic operation, [APIC390\[Count\]](#) is reloaded with the [APIC380\[Count\]](#) value, and it continues to decrement at the rate of the divided clock. If [APIC320\[Mask\]](#) is set, timer interrupts are not generated.

2.4.8.1.14 Generalized Local Vector Table

All LVTs ([APIC330](#) to [APIC3\[60:50\]](#), and [APIC\[530:500\]](#)) support a generalized message type as follows:

- 000b=Fixed
- 010b=SMI
- 100b=NMI
- 111b=ExtINT
- All other messages types are reserved.

2.4.8.1.15 State at Reset

At power-up or reset, the APIC is hardware disabled ([MSR0000_001B\[ApicEn\]](#)=0) so only SMI, NMI, INIT, and ExtInt interrupts may be accepted.

The APIC can be software disabled through [APICF0\[APICSWEn\]](#). The software disable has no effect when the APIC is hardware disabled.

When a processor accepts an INIT interrupt, the APIC is reset as at power-up, with the exception that:

- [APIC20\[ApicId\]](#) is unaffected.
- Pending APIC register writes complete.

2.4.8.2 System Management Mode (SMM)

System management mode (SMM) is typically used for system control activities such as power management. These activities are typically transparent to the operating system.

2.4.8.2.1 SMM Overview

SMM is entered by a core on the next instruction boundary after a system management interrupt (SMI) is received and recognized. A core may be programmed to broadcast a special cycle to the system, indicating that it is entering SMM mode. The core then saves its state into the SMM memory state save area and jumps to the SMI service routine (or SMI handler). The pointer to the SMI handler is specified by MSRs. The code and data for the SMI handler are stored in the SMM memory area, which may be isolated from the main memory accesses.

The core returns from SMM by executing the RSM instruction from the SMI handler. The core restores its state from the SMM state save area and resumes execution of the instruction following the point where it entered SMM. The core may be programmed to broadcast a special bus cycle to the system, indicating that it is exiting SMM mode.

2.4.8.2.2 Operating Mode and Default Register Values

The software environment after entering SMM has the following characteristics:

- Addressing and operation is in Real mode.
 - A far jump, call or return in the SMI handler can only address the lower 1M of memory, unless the SMI handler first switches to protected mode.
 - If ([MSRC001_0111](#)[SmmBase]>=0010_0000h) then:
 - The value of the CS selector is undefined upon SMM entry.
 - The undefined CS selector value should not be used as the target of a far jump, call, or return.
- 4-Gbyte segment limits.
- Default 16-bit operand, address, and stack sizes (instruction prefixes can override these defaults).
- Control transfers that do not override the default operand size truncate the EIP to 16 bits.
- Far jumps or calls cannot transfer control to a segment with a base address requiring more than 20 bits, as in Real mode segment-base addressing, unless a change is made into protected mode.
- A20M# is disabled. A20M# assertion or deassertion have no affect during SMM.
- Interrupt vectors use the Real mode interrupt vector table.
- The IF flag in EFLAGS is cleared (INTR is not recognized).
- The TF flag in EFLAGS is cleared.
- The NMI and INIT interrupts are masked.
- Debug register DR7 is cleared (debug traps are disabled).

The SMM base address is specified by [MSRC001_0111](#)[SmmBase]. Important offsets to the base address pointer are:

- [MSRC001_0111](#)[SmmBase] + 8000h: SMI handler entry point.
- [MSRC001_0111](#)[SmmBase] + FE00h - FFFFh: SMM state save area.

2.4.8.2.3 SMI Sources And Delivery

The processor accepts SMIs as link-defined interrupt messages only. The core/node destination of these SMIs is a function of the destination field of these messages. However, the expectation is that all such SMI messages are specified to be delivered globally (to all cores of all nodes).

There are also several local events that can trigger SMIs. However, these local events do not generate SMIs directly. Each of them triggers a programmable IO cycle that is expected to target the SMI command port in the IO hub and trigger a global SMI interrupt message back to the coherent fabric.

Local sources of SMI events that generate the IO cycle specified in [MSRC001_0056](#) [SMI Trigger IO Cycle] are:

- In the core, as specified by:
 - [MSRC001_0022](#) [Machine Check Exception Redirection].
 - [MSRC001_00](#)[53:50] [IO Trap (SMI_ON_IO_TRAP_[3:0])].
- All local APIC LVT registers programmed to generate SMIs.

The status for these is stored in [SMMFEC4](#).

2.4.8.2.4 SMM Initial State

After storing the save state, execution starts at [MSRC001_0111](#)[SmmBase] + 08000h. The SMM initial state is specified in the following table.

Table 6: SMM Initial State

Register	SMM Initial State
CS	SmmBase[19:4]
DS	0000h
ES	0000h
FS	0000h
GS	0000h
SS	0000h
General-Purpose Registers	Unmodified (including CR2, CR3, CR8)
EFLAGS	0000_0002h
RIP	0000_0000_0000_8000h
CR0	Bits 0, 2, 3, and 31 cleared (PE, EM, TS, and PG); remainder is unmodified
CR4	0000_0000_0000_0000h
GDTR	Unmodified
LDTR	Unmodified
IDTR	Unmodified
TR	Unmodified
DR6	Unmodified
DR7	0000_0000_0000_0400h
EFER	All bits are cleared except bit 12 (SVME) which is unmodified.

2.4.8.2.5 SMM Save State

In the following table, the offset field provides the offset from the SMM base address specified by [MSRC001_0111 \[SMM Base Address \(SMM_BASE\)\]](#).

Table 7: SMM Save State

Offset	Size	Contents		Access
FE00h	Word	ES	Selector	Read-only
FE02h	6 Bytes		Reserved

FFF8h	Quadword	RAX	

Notes:

1. This notation specifies that bit[47] is replicated in each of the 16 MSBs of the DW (sometimes called *sign extended*). The 16 LSB's contain bits[47:32].
2. Only used for an SMI in guest mode with nested paging enabled. Used to control the table walker.

The SMI save state includes most of the integer execution unit. Not included in the save state are: the floating point state, MSRs, and CR2. In order to be used by the SMI handler, these must be saved and restored. The save state is the same, regardless of the operating mode (32-bit or 64-bit).

The following are some offsets in the SMM save state area. The mnemonic for each offset is in the form SMMxxxx, where xxxx is the offset in the save state.

SMMFEC0 SMM IO Trap Offset

If the assertion of SMI is recognized on the boundary of an IO instruction, [SMMFEC0 \[SMM IO Trap Offset\]](#) contains information about that IO instruction. For example, if an IO access targets an unavailable device, the system can assert SMI and trap the IO instruction. [SMMFEC0](#) then provides the SMI handler with information about the IO instruction that caused the trap. After the SMI handler takes the appropriate action, it can reconstruct and then re-execute the IO instruction from SMM. Or, more likely, it can use [SMMFEC8 \[SMM IO Restart Byte\]](#), to cause the core to re-execute the IO instruction immediately after resuming from SMM.

Bits	Description
31:16	Port: trapped IO port address. Read-only. This provides the address of the IO instruction.
15:12	BPR: IO breakpoint match. Read-only.
11	TF: EFLAGS TF value. Read-only.
10:7	Reserved.
6	SZ32: size 32 bits. Read-only. 1=Port access was 32 bits.
5	SZ16: size 16 bits. Read-only. 1= Port access was 16 bits.
4	SZ8: size 8 bits. Read-only. 1=Port access was 8 bits.
3	REP: repeated port access. Read-only.
2	STR: string-based port access. Read-only.
1	V: IO trap word valid. Read-only. 1=The core entered SMM on an IO instruction boundary; all information in this offset is valid. 0=The other fields of this offset are not valid.
0	RW: port access type. Read-only. 0=IO write (OUT instruction). 1=IO read (IN instruction).

SMMFEC4 Local SMI Status

This offset stores status bits associated with SMI sources local to the core. For each of these bits, 1=The associated mechanism generated an SMI.

Bits	Description
17	SmiSrcLvtExt: SMI source LVT extended entry. Read-only. This bit is associated with the SMI sources specified in APIC[530:500] [Extended Interrupt [3:0] Local Vector Table] .
16	SmiSrcLvtLcy: SMI source LVT legacy entry. Read-only. This bit is associated with the SMI sources specified by the non-extended LVT entries of the APIC.
15:9	Reserved.
8	MceRedirSts: machine check exception redirection status. Read-only. This bit is associated with the SMI source specified in MSRC001_0022[RedirSmiEn] .
3:0	IoTrapSts: IO trap status. Read-only. Each of these bits is associated with each of the respective SMI sources specified in MSRC001_00[53:50] [IO Trap (SMI_ON_IO_TRAP_[3:0])] .

SMMFEC8 SMM IO Restart Byte

00h on entry into SMM.

If the core entered SMM on an IO instruction boundary, the SMI handler may write this to FFh. This causes the core to re-execute the trapped IO instruction immediately after resuming from SMM. The SMI handler should only write to this byte if **SMMFEC0** field V==1; otherwise, the behavior is undefined.

If a second SMI is asserted while a valid IO instruction is trapped by the first SMI handler, the core services the second SMI prior to re-executing the trapped IO instruction. **SMMFEC0** field V==0 during the second entry into SMM, and the second SMI handler must not rewrite this byte.

If there is a simultaneous SMI IO instruction trap and debug breakpoint trap, the processor first responds to the SMI and postpones recognizing the debug exception until after resuming from SMM. If debug registers other than DR6 and DR7 are used while in SMM, they must be saved and restored by the SMI handler. If **SMMFEC8 [SMM IO Restart Byte]**, is set to FFh when the RSM instruction is executed, the debug trap does not occur until after the IO instruction is re-executed.

Bits	Description
7:0	RST: SMM IO Restart Byte. Read-write.

SMMFEC9 Auto Halt Restart Offset

Bits	Description
7:1	Reserved.
0	HLT: halt restart. Read-write. Upon SMM entry, this bit indicates whether SMM was entered from the Halt state. 0=Entered SMM on a normal x86 instruction boundary. 1=Entered SMM from the Halt state. Before returning from SMM, this bit can be written by the SMI handler to specify whether the return from SMM should take the processor back to the Halt state or to the instruction-execution state specified by the SMM state save area (normally, the instruction after the halt). 0=Return to the instruction specified in the SMM save state. 1=Return to the halt state. If the return from SMM takes the processor back to the Halt state, the HLT instruction is not refetched and re-executed. However, the Halt special bus cycle is broadcast and the processor enters the Halt state.

SMMFECA NMI Mask

Bits	Description
7:1	Reserved.
0	NmiMask. Read-write. Specifies whether NMI was masked upon entry to SMM. 0=NMI not masked. 1=NMI masked.

SMMFED8 SMM SVM State

Read-only. This offset stores the SVM state of the processor upon entry into SMM.

Bits	Description
63:4	Reserved.

3	HostEflagsIf: host Eflags IF.														
2:0	SvmState. <table> <tr> <th>Bits</th><th>Definition</th></tr> <tr> <td>000b</td><td>SMM entered from a non-guest state.</td></tr> <tr> <td>001b</td><td>Reserved.</td></tr> <tr> <td>010b</td><td>SMM entered from a guest state.</td></tr> <tr> <td>101b-011b</td><td>Reserved.</td></tr> <tr> <td>110b</td><td>SMM entered from a guest state with nested paging enabled.</td></tr> <tr> <td>111b</td><td>Reserved.</td></tr> </table>	Bits	Definition	000b	SMM entered from a non-guest state.	001b	Reserved.	010b	SMM entered from a guest state.	101b-011b	Reserved.	110b	SMM entered from a guest state with nested paging enabled.	111b	Reserved.

SMMFEFC SMM-Revision Identifier

SMM entry state: 0003_0064h

Bits	Description
31:18	Reserved.
17	BRL. Read-only. Base relocation supported.
16	IOTrap. Read-only. IO trap supported.
15:0	Revision. Read-only.

SMMFF00 SMM Base Address (SMM_BASE)

Bits	Description
31:0	See: MSRC001_0111 [SmmBase].

2.4.8.2.6 Exceptions and Interrupts in SMM

When SMM is entered, the core masks INTR, NMI, SMI, INIT, and A20M interrupts. The core clears the IF flag to disable INTR interrupts. To enable INTR interrupts within SMM, the SMM handler must set the IF flag to 1. A20M is disabled so that address bit 20 is never masked when in SMM.

Generating an INTR interrupt can be used for unmasking NMI interrupts in SMM. The core recognizes the assertion of NMI within SMM immediately after the completion of an IRET instruction. Once NMI is recognized within SMM, NMI recognition remains enabled until SMM is exited, at which point NMI masking is restored to the state it was in before entering SMM.

While in SMM, the core responds to the DBREQ and STPCLK interrupts, as well as to all exceptions that may be caused by the SMI handler.

2.4.8.2.7 The Protected ASeg and TSeg Areas

These ranges are controlled by [MSRC001_0112](#) and [MSRC001_0113](#); see those registers for details.

2.4.8.2.8 SMM Special Cycles

Special cycles can be initiated on entry and exit from SMM to acknowledge to the system that these transitions are occurring. These are controlled by [MSRC001_0015](#)[RsmSpCycDis, SmiSpCycDis].

2.4.8.2.9 Locking SMM

The SMM registers ([MSRC001_0112](#) and [MSRC001_0113](#)) can be locked from being altered by setting [MSRC001_0015](#)[SmmLock]. SBIOS must lock the SMM registers after initialization to prevent unexpected changes to these registers.

2.4.8.2.10 Synchronizing SMM Entry (Spring-Boarding)

The BIOS must take special care to ensure that all cores have entered SMM prior to accessing shared IO resources and all core SMI interrupt status bits are synchronized. This generally requires that BIOS waits for all cores to enter SMM.

The following conditions can cause one or more cores to enter SMM without all cores entering SMM:

- More than one IO device in the system is enabled to signal an SMI without hardware synchronization (e.g. using an end of SMI gate).
- A single device may signal multiple SMI messages without hardware synchronization (e.g. using an end of SMI gate).
- An SMI is received while one or more AP cores are in the INIT state. This may occur either during BIOS or secure boot.
- A hardware error prevents a core from entering SMM.

The act of synchronizing cores into SMM is called spring-boarding. Because not all of the above conditions can be avoided, it is recommended that all systems support spring-boarding.

An ACPI-compliant IO hub is required for spring-boarding. Depending on the IO hub design, BIOS may have to set additional end-of-SMI bits to trigger an SMI from within SMM.

The software requirements for the suggested spring-boarding implementation are listed as follows.

- A binary semaphore located in SMRAM, accessible by all cores. For the purpose of this discussion, the semaphore is called CheckSpringBoard. CheckSpringBoard is initialized to zero.
- Two semaphores located in SMRAM, accessible by all cores. For the purpose of this discussion, the semaphores are called NotInSMM and WaitInSMM. NotInSMM and WaitInSMM are initialized to a value equal to the number of cores in the system (NumCPUs).

The following BIOS algorithm describes spring-boarding and is optimized to reduce unnecessary SMI activity. This algorithm must be made part of the SMM instruction sequence for each core in the system.

1. Attempt to obtain ownership of the CheckSpringBoard semaphore with a read-modify-write instruction. If ownership was obtained then do the following, else proceed to step 2:
 - Check all enabled SMI status bits in the IO hub.
Let Status=enable1&status1 | enable2&status2 | enable3&status3 ... enable n & status n.
 - If (Status==0) then perform the following sub-actions.
 - Trigger an SMI broadcast assertion from the IO hub by writing to the software SMI command port.
 - Resume from SMM with the RSM instruction.
- //Example:
- ```
InLineASM{
 BTS CheckSpringBoard,0; Try to obtain ownership of semaphore
 JC Step_2:
 CALL CheckIOHUB_SMIEVT; proc returns ZF=1 for no events
 JNZ Step_2:
 CALL Do_SpringBoard;Trigger SMI and then RSM
```

```

 Step_2:
}

```

2. Decrement the NotInSMM variable. Wait for (NotInSMM==0). See Note 1.
3. Execute the core-local event SMI handler. Using a third semaphore (not described here), synchronize core execution at the end of the task. After all cores have executed, proceed to step 4. The following is a brief description of the task for each core:
  - Check all enabled core-local SMI status bits in the core's private or MSR address space. Handle the event if possible, or pass information necessary to handle the event to a mailbox for the BSC to handle.
  - An exclusive mailbox must exist for each core for each core local event.
  - Wait for all cores to complete this task at least once.
4. If the current core executing instructions is not the BSC then jump to step 5. If the core executing instructions is the BSC then jump to the modified main SMI handler task, described below.
  - Check all enabled SMI status bits in the IO hub. Check mailboxes for event status.
  - For each event, handle the event and clear the corresponding status bit.
  - Repeat until all enabled SMI status bits are clear and no mailbox events remain.
  - Set NotInSMM=NumCPUs. (Jump to step 5.)
5. Decrement the WaitInSMM variable. Wait for WaitInSMM=0. See Note 2.
6. Increment the WaitInSMM variable. Wait for WaitInSMM=NumCPUs.
7. If the current processor core executing instructions is the BSC then reset CheckSpringBoard to zero.
8. Resume from SMM with the RSM instruction.

#### Notes:

1. To support a secure startup by the secure loader the BIOS must provide a timeout escape from the otherwise endless loop. The timeout value should be large enough to account for the latency of all cores entering SMM. The maximum SMM entrance latency is defined by the platform's IO sub-system, not the processor. A value of twice the watchdog timer count is recommended. See [D18F3x44 \[MCA NB Configuration\]](#) for more information on the watchdog time-out value. If a time-out occurs in the wait loop, the BIOS (the last core to decrement NotInSMM) should record the number of cores that have not entered SMM and all cores must fall out of the loop.
2. If a time-out occurs in the wait loop in step 2, the BIOS must not wait for WaitInSMM=0. Instead it must wait for WaitInSMM=(the number of cores recorded in step 2).
3. If BIOS places APs in the INIT state during any part of the boot process when SMIs may be generated, or may generate SMIs before taking all APs out of their initial microcode reset loop (i.e., before [D18F0x1DC\[CpuEn\]](#) is set), then it is recommended that BIOS keep a record of how many APs are in these two states and exclude these cores from the wait loops. SMIs are not recognized by a processor in these states. AMD does not recommend enabling SMI sources prior to bringing all APs out of these states.

## 2.4.9 Secure Virtual Machine Mode (SVM)

Support for SVM mode is indicated by [CPUID Fn8000\\_0001\\_ECX\[SVM\]](#).

### 2.4.9.1 BIOS support for SVM Disable

The BIOS should include the following user setup options to enable and disable AMD Virtualization™ technology.

- Enable AMD Virtualization™.
  - [MSRC001\\_0114\[SvmeDisable\]](#) = 0.
  - [MSRC001\\_0114\[Lock\]](#) = 1.
  - [MSRC001\\_0118\[SvmLockKey\]](#) = 0000\_0000\_0000\_0000h.
- Disable AMD Virtualization™.

- [MSRC001\\_0114](#)[SvmeDisable]=1.
- [MSRC001\\_0114](#)[Lock]=1.
- [MSRC001\\_0118](#)[SvmLockKey] = 0000\_0000\_0000\_0000h.

The BIOS may also include the following user setup options to disable AMD Virtualization™ technology.

- Disable AMD Virtualization™, with a user supplied key.
  - [MSRC001\\_0114](#)[SvmeDisable]=1.
  - [MSRC001\\_0114](#)[Lock]=1.
  - [MSRC001\\_0118](#)[SvmLockKey] programmed with value supplied by user. This value should be stored in NVRAM.

#### 2.4.10 CPUID Instruction

The CPUID instruction provides data about the features supported by the processor. See [3.18 \[CPUID Instruction Registers\]](#).

##### 2.4.10.1 Multi-Core Support

There are two methods for determining multi-core support. A recommended mechanism is provided and a legacy method is also available for existing operating systems. System software should use the correct architectural mechanism to detect the number of physical cores by observing [CPUID Fn8000\\_0008\\_ECX](#)[NC]. The legacy method utilizes the [CPUID Fn0000\\_0001\\_EBX](#)[LogicalProcessorCount].

## 2.5 Power Management

The processor supports many power management features in a variety of systems. [Table 8](#) provides a summary of ACPI states and power management features and indicates whether they are supported.

**Table 8: Power Management Support**

| ACPI/Power Management State                                      | Supported | Description                                                                                |
|------------------------------------------------------------------|-----------|--------------------------------------------------------------------------------------------|
| G0/S0/C0: Working                                                | Yes       |                                                                                            |
| G0/S0/C0: Core P-state transitions                               | Yes       | <a href="#">2.5.3.1 [Core P-states]</a>                                                    |
| G0/S0/C0: NB P-state transitions                                 | Yes       | <a href="#">2.5.4.1 [NB P-states]</a>                                                      |
| G0/S0/C0: Hardware thermal control (HTC)                         | Yes       | <a href="#">2.10.3.1 [PROCHOT_L and Hardware Thermal Control (HTC)]</a>                    |
| G0/S0/Per-core IO-based C-states                                 | Yes       | <a href="#">2.5.3.2 [Core C-states]</a> and <a href="#">2.5.1.3.2 [Low Power Voltages]</a> |
| G0/S0/C1: Halt                                                   | Yes       |                                                                                            |
| G0/S0/CC6: Per-core Power gating                                 | Yes       | <a href="#">2.5.3.2 [Core C-states]</a>                                                    |
| G0/S0/XC6: CPC-L2 power gating                                   | Yes       | <a href="#">2.5.3.2 [Core C-states]</a> and <a href="#">2.5.5.2.3.5 [XC6 State]</a>        |
| G0/S0/PC6: 0V support (VDD power plane).                         | Yes       | <a href="#">2.5.3.2 [Core C-states]</a> and <a href="#">2.5.1.3.2 [Low Power Voltages]</a> |
| G0/S0/Cx: Cache flushing support                                 | Yes       | <a href="#">2.5.3.2.3.1 [C-state Probes and Cache Flushing]</a>                            |
| G0/S0: Northbridge C-states (DRAM self-refresh, NB clock-gating) | Yes       | <a href="#">2.5.4.2 [NB C-states]</a>                                                      |
| G1/S1: Stand By (Powered On Suspend)                             | No        |                                                                                            |
| G1/S3: Stand By (Suspend to RAM)                                 | Yes       | <a href="#">2.5.8.1 [S-states]</a>                                                         |
| G1/S4: Hibernate (Suspend to Disk)                               | Yes       |                                                                                            |
| G1/S5: Shut Down (Soft Off)                                      | Yes       |                                                                                            |
| G3 Mechanical Off                                                | Yes       |                                                                                            |
| Parallel VID Interface                                           | No        | <a href="#">2.5.1 [Processor Power Planes And Voltage Control]</a>                         |

### 2.5.1 Processor Power Planes And Voltage Control

Refer to the *Electrical Data Sheet* and the *AMD Infrastructure Roadmap* for power plane definitions. See [1.2 \[Reference Documents\]](#).

#### 2.5.1.1 Serial VID Interface

The processor includes an interface to control external voltage regulators, called the serial VID interface (SVI). Both SVI1 and SVI2 are supported. On PWROK assertion, the SVT pin is sampled by the processor to determine the SVI mode supported by the voltage regulator. If SVT is high the processor uses SVI2 mode, otherwise the processor uses SVI1 mode. The default frequency for SVI1 is 3.4MHz. The frequency of SVC for SVI2 is controlled by [D18F3xA0\[Svi2HighFreqSel\]](#). See the *AMD Voltage Regulator Specification* and the *AMD Serial VID Interface 2.0 (SVI2) Specification* for additional details.

### 2.5.1.1.1 SVI2 Features

The processor supports the following SVI2 features:

- Voltage offsets:
  - VDD: **D18F5x12C**[CoreOffsetTrim], **D0F0xBC\_x3F9F8**[SviLoadLineOffsetVdd]. Changes to either register must be reflected in both locations.
  - VDDNB: **D18F5x188**[NbOffsetTrim], **D0F0xBC\_x3F9F8**[SviLoadLineOffsetVddNB]. Changes to either register must be reflected in both locations.
- Load line trim:
  - VDD: **D18F5x12C**[CoreLoadLineTrim], **D0F0xBC\_x3F9F4**[SviTrimValueVdd]. Changes to either register must be reflected in both locations.
  - VDDNB: **D18F5x188**[NbLoadLineTrim], **D0F0xBC\_x3F9F4**[SviTrimValueVddNB]. Changes to either register must be reflected in both locations.

### 2.5.1.2 Internal VID Registers and Encodings

All VID register fields within the processor are 8-bits wide. When using SVI1, VID encodings are 7-bits wide and the least significant bit is ignored. In SVI2 all 8 bits are used. The VID encodings to voltage translation for all VID codes are defined by the SVI mode. See the *AMD Voltage Regulator Specification* and the *AMD Serial VID Interface 2.0 (SVI2) Specification* for additional details.

The boot VID is 1.0 volts.

#### 2.5.1.2.1 MinVid and MaxVid Check

Hardware limits the minimum and maximum VID code that is sent to the voltage regulator. The allowed limits are specified in **D18F5x17C**[MinVid, MaxVid]. Prior to generating VID-change commands to SVI, the processor filters the InputVid value to the OutputVid as follows (higher VID codes correspond to lower voltages and lower VID codes correspond to higher voltages):

- If InputVid < MaxVid, OutputVid=MaxVid.
  - Else if (InputVid > MinVid) & (MinVid!=00h), OutputVid=MinVid.
  - Else OutputVid=InputVid.

This filtering is applied regardless of the source of the VID-change command, except for THERMTRIP which applies Fuse[ThermVid] irrespective of MinVid.

### 2.5.1.3 Low Power Features

#### 2.5.1.3.1 PSIx\_L Bit

The processor can indicate whether or not it's in a low-voltage state via the PSIx\_L bit. This indicator may be used by the voltage regulator to place itself into a more power efficient mode. PSIx\_L is controlled independently for VDD and VDDNB. Support for PSIx\_L varies with the SVI mode as follows:

- SVI2: The processor supports the PSIO\_L and the PSI1\_L bits in the data fields of the SVI2 command.
  - PSIO\_L: PSIO\_L for VDD and VDDNB is enabled using **D18F3xA0**[PsiVidEn] and **D18F5x17C**[NbPsi0VidEn], respectively. Once enabled, the state of PSIO\_L is controlled by **D18F3xA0**[PsiVid[7:0]] and **D18F5x17C**[NbPsi0Vid]. Changes to the state of PSIO\_L can only occur on VID changes.

- **PSI1\_L:** The PSI1\_L bit for VDD and VDDNB is specified by [D18F5x12C](#)[CorePsi1En] and [D0F0xBC\\_x3F9EC](#)[EnableNbPsi1], respectively. See also [D18F5x188](#)[NbPsi1]. Changes to the state of PSI1\_L can occur at any time.

### 2.5.1.3.1.1 BIOS Requirements for PSI0\_L

Enabling PSI0\_L for the VDD and VDDNB planes depends on support from the voltage regulator and is therefore system specific. The voltage regulator must be able to supply the current required for the processor to operate at the VID code specified in [D18F3xA0](#)[PsiVid[7:0]] and [D18F5x17C](#)[NbPsi0Vid[7:0]]. Depending on the regulator used, AMD recommends one of the following methods:

- **PSI0\_L disabled:**
  - **VDD:** To set PSI0\_L for the VDD plane, program [D18F3xA0](#)[PsiVidEn]=0.
  - **VDDNB:** To set PSI0\_L for the VDDNB plane, program [D18F5x17C](#)[NbPsi0VidEn]=0.
- **PSI0\_L set/clear based on current requirements:**
  - **VDD:** The following algorithm describes how to program PSI0\_L on VDD:

PSI\_vrm\_current = current at which the regulator allows PSI0\_L. Refer to parameter BLDCFG\_VRM\_LOW\_POWER\_THRESHOLD in AMD Generic Encapsulated Software Architecture (AGESA) Interface Specification, order #44065.

```
previous_voltage = FFh

for (each P-state from P0 to D18F3xDC[HwPstateMaxVal]) {
 pstate_current = ProcIddMax for the current P-state,
 see 2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\];
 pstate_voltage = MSRC001_00[6B:64][CpuVid] of the current P-state;

 if (current P-state == D18F3xDC[HwPstateMaxVal]) {
 next_pstate_current = 0;
 } else {
 next_pstate_current = ProcIddMax for the next P-state,
 see 2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\];
 }

 if ((pstate_current <= PSI_vrm_current) &&
 (next_pstate_current <= PSI_vrm_current) &&
 (pstate_voltage != previous_voltage)) {
 Program D18F3xA0[PsiVid] = pstate_voltage;
 Program D18F3xA0[PsiVidEn] = 1;
 break;
 }
 previous_voltage = pstate_voltage;
}
```

- **VDDNB:** The following algorithm describes how to program PSI0\_L on VDDNB:

NbIddMax = [D18F5x16](#)[C:0][NbIddDiv] current.

PSI\_vrm\_current = current at which the VDDNB regulator allows PSI0\_L. Refer to parameter BLDCFG\_VRM\_NB\_LOW\_POWER\_THRESHOLD in AMD Generic Encapsulated Software Architecture (AGESA) Interface Specification, order #44065.

```
previous_voltage = FFh

for (each valid NB P-state starting with NBP0) {
 pstate_current = NbIddMax of the current NB P-state;
 pstate_voltage = D18F5x16[C:0][NbVid] of the current NB P-state;
```

```

 if (current P-state is the last valid P-state) {
 next_pstate_current = 0;
 } else {
 next_pstate_current = NbIddMax for the next P-state;
 }

 if ((pstate_current <= PSI_vrm_current) &&
 (next_pstate_current <= PSI_vrm_current) &&
 (pstate_voltage != previous_voltage)) {
 Program D18F5x17C[NbPsi0Vid] = pstate_voltage;
 Program D18F5x17C[NbPsi0VidEn] = 1;
 break;
 }
 previous_voltage = pstate_voltage;
}

```

### 2.5.1.3.2 Low Power Voltages

In order to save power, voltages lower than those normally needed for operation may be applied to the VDD power plane while the processor is in a C-state or S-state. The lower voltages are defined as follows:

- PC6Vid: D18F5x128[PC6Vid] specifies a voltage that does not retain the CPU caches or the core microarchitectural state. PC6Vid does not allow execution and is only applied to the cores. See 2.5.3.2.3.4 [Package C6 (PC6) State].

### 2.5.1.4 Voltage Transitions

The processor supports dynamic voltage transitions on the VDD and VDDNB planes. These transitions are requested by either hardware or software during state changes such as reset, P-state changes, and C-state changes. In all cases the VID code passed to the voltage regulator changes from the old value to the new value without stepping through intermediate values. The voltage regulator ramps the voltage directly from the starting voltage to the final voltage, no stepping occurs. See the *AMD Voltage Regulator Specification* and the *AMD Serial VID Interface 2.0 (SVI2) Specification* for additional details.

- If a voltage increase is requested in SVI2, the processor waits the amount of time specified by D18F5x12C[WaitVidCompDis] before sending any additional voltage change requests to the voltage regulator or before beginning a frequency transition.
- If a voltage decrease is requested, the processor waits the amount of time specified by D18F5x128[FastSlamTimeDown] before sending any additional voltage change requests to the voltage regulator. For voltage decreases, the processor does not wait any time before beginning frequency changes.

The processor continues code execution during voltage changes when in the C0 state.

#### 2.5.1.4.1 Hardware-Initiated Voltage Transitions

When software requests any of the following state changes, or hardware determines that any of the following state changes are necessary, hardware coordinates the necessary voltage changes:

- VDD:
  - Core P-state transition. See 2.5.3.1 [Core P-states].
  - Package C-state transition. D18F5x128[PC6Vid] specifies a voltage that does not retain the CPU caches or the core microarchitectural state. PC6Vid does not allow execution and is only applied to the cores.

See [2.5.3.2.3.4 \[Package C6 \(PC6\) State\]](#).

- S-state transition. See [2.5.8.1 \[S-states\]](#).

- VDDNB:

- NB P-state transition. See [2.5.4.1 \[NB P-states\]](#).
- S-state transition. See [2.5.8.1 \[S-states\]](#).

## 2.5.1.4.2 Software-Initiated Voltage Transitions

### 2.5.1.4.2.1 Software-Initiated NB Voltage Transitions

Software can request voltage changes on the VDDNB power plane using the BIOSMC\_MSG\_VDDNB\_REQUEST software interrupt. To make a voltage change request, software uses the sequence described in [2.12.1 \[Software Interrupts\]](#) with Service Index 3Ah. This request is evaluated with other VDDNB requests within GNB as mentioned below.

Software voltage requests are considered by hardware when taking voltage plane dependencies into account (see [2.5.2.2 \[Dependencies Between Subcomponents on VDDNB\]](#)).

## 2.5.2 Frequency and Voltage Domain Dependencies

### 2.5.2.1 Dependencies Between Cores

Whenever a P-state or C-state is requested on a core (see [2.5.3.1 \[Core P-states\]](#) and [2.5.3.2 \[Core C-states\]](#)), hardware must take the following frequency and voltage domain dependencies into account when deciding whether to make the requested change:

- Cores within a compute unit share a common frequency and voltage domain.
- Compute units within a processor share a common voltage domain, but have independent frequency domains. The voltage is determined by the highest-performance P-state requested on any core.

As a result, the P-state and C-state change requests have the following results:

- If different compute units request different voltages, the VDD voltage is determined by the highest voltage (lowest VID) requested.
- If the cores within a compute unit request different P-states while in C0, frequency and voltage are determined by the highest-performance P-state requested.
- If both cores request non-C0 states, the behavior is specified by [D18F4x128\[CoreCstatePolicy\]](#).
- If one core within a compute unit requests a CC6 while the other core is in C0, the frequency and voltage of the compute unit is determined by the core in C0.
- If one core within a compute unit requests a CC6 while the other core is in C0, the core could independently enter CC6.

### 2.5.2.2 Dependencies Between Subcomponents on VDDNB

Many subcomponents of the processor reside on the VDDNB power plane. Hardware must take voltage domain dependencies into account when determining whether to make a voltage change requested by one of the subcomponents. Whenever a state transition occurs that causes a voltage change request (see [2.5.1.4.1 \[Hardware-Initiated Voltage Transitions\]](#)), or software makes a voltage change request (see [2.5.1.4.2 \[Software-Initiated Voltage Transitions\]](#)), the VDDNB voltage requested by the processor is determined by the highest voltage (lowest VID) request made by any of the subcomponents or by software. GNB voltage requests can be ignored by NB voltage controller via [D18F5x178\[GnbVidReqDis\]](#).

### 2.5.2.3 BIOS Requirements for Power Plane Initialization

- Ensure the following fields are configured to their BIOS recommendations:
  - [D18F3xA0](#)[Svi2HighFreqSel, SviHighFreqSel].
  - [D18F3xD8](#)[VSRampSlamTime].
- Optionally configure PSIx\_L. Refer to [2.5.1.3.1 \[PSIx\\_L Bit\]](#) for additional details.

## 2.5.3 CPU Power Management

### 2.5.3.1 Core P-states

Core P-states are operational performance states characterized by a unique combination of core frequency and voltage. The processor supports up to 8 core P-states (P0 through P7), specified in [MSRC001\\_00\[6B:64\]](#). Out of cold reset, the voltage and frequency of the compute units is specified by [MSRC001\\_0071](#)[StartupPstate] and [D18F3xA0](#)[CofVidProg].

Support for dynamic core P-state changes is indicated by more than one enabled selection in [MSRC001\\_00\[6B:64\]](#)[PstateEn]. At least one enabled P-state (P0) is specified for all processors.

Software requests core P-state changes for each core independently using the hardware P-state control mechanism (a.k.a. fire and forget). Support for hardware P-state control is indicated by [CPUID Fn8000\\_0007\\_EDX](#)[HwPstate]=1b. Software may not request any P-state transitions using the hardware P-state control mechanism until the P-state initialization requirements defined in [2.5.3.1.6 \[BIOS Requirements for Core P-state Initialization and Transitions\]](#) are complete.

The processor supports independently-controllable frequency planes for each compute unit and the NB; and independently-controllable voltage planes. See [2.5.1 \[Processor Power Planes And Voltage Control\]](#) for voltage plane definitions and [1.5.4 \[Supported Feature Variations\]](#) for package/socket-specific information on voltage plane compatibility.

The following terms may be applied to each of these planes:

- FID: frequency ID. Specifies the PLL frequency multiplier, relative to the reference clock, for a given domain.
- DID: divisor ID. Specifies the post-PLL power-of-two divisor that can be used to reduce the operating frequency.
- COF: current operating frequency. Specifies the operating frequency as a function of the FID and DID. Refer to [CoreCOF](#) for the CPU COF formula and [NBCOF](#) for the NB COF formula.
- VID: voltage ID. Specifies the voltage level for a given domain. Refer to [2.5.1.2.1 \[MinVid and MaxVid Check\]](#) for encodings.

All FID and DID parameters for software P-states must be programmed to equivalent values for all cores and NBs in the coherent fabric. See [2.5.3.1.1.1 \[Software P-state Numbering\]](#). Refer to [MSRC001\\_00\[6B:64\]](#) and [D18F5x16\[C:0\]](#) for further details on programming requirements.

#### 2.5.3.1.1 Core P-state Naming and Numbering

Since the number of boosted P-states may vary from product to product, the mapping between [MSRC001\\_00\[6B:64\]](#) and the indices used to request P-state changes or status also varies. In order to clarify this, two different numbering schemes are used.

### 2.5.3.1.1.1 Software P-state Numbering

When referring to software P-state numbering, the following naming convention is used:

- Non-boosted P-states are referred to as P0, P1, etc.
  - P0 is the highest power, highest performance, non-boosted P-state.
  - Each ascending P-state number represents a lower-power, lower performance non-boosted P-state than the prior P-state number.
- Boosted P-states are referred to as Pb0, Pb1, etc.
  - Pb0 is the highest-performance, highest-power boosted P-state.
  - Each higher numbered boosted P-state represents a lower-power, lower-performance boosted P-state.

For example, if [D18F4x15C](#)[NumBoostStates] contains the values shown below, then the P-states would be named as follows:

**Table 9: Software P-state Naming**

| <a href="#">D18F4x15C</a> [NumBoostStates]=1 |                           | <a href="#">D18F4x15C</a> [NumBoostStates]=3 |                           |
|----------------------------------------------|---------------------------|----------------------------------------------|---------------------------|
| P-state Name                                 | Corresponding MSR Address | P-state Name                                 | Corresponding MSR Address |
| Pb0                                          | MSRC001_0064              | Pb0                                          | MSRC001_0064              |
| P0                                           | MSRC001_0065              | Pb1                                          | MSRC001_0065              |
| P1                                           | MSRC001_0066              | Pb2                                          | MSRC001_0066              |
| P2                                           | MSRC001_0067              | P0                                           | MSRC001_0067              |
| P3                                           | MSRC001_0068              | P1                                           | MSRC001_0068              |
| P4                                           | MSRC001_0069              | P2                                           | MSRC001_0069              |
| P5                                           | MSRC001_006A              | P3                                           | MSRC001_006A              |
| P6                                           | MSRC001_006B              | P4                                           | MSRC001_006B              |

All sections and register definitions use software P-state numbering unless otherwise specified.

### 2.5.3.1.1.2 Hardware P-state Numbering

When referring to hardware P-state numbering, the following naming convention is used:

- All P-states are referred to as P0, P1, etc.
  - P0 is the highest power, highest-performance P-state, regardless of whether it is a boosted P-state or a non-boosted P-state.
  - Each ascending P-state number represents a lower-power, lower-performance P-state, regardless of whether it is a boosted P-state or not.

### 2.5.3.1.2 Core P-state Control

Core P-states are dynamically controlled by software and are exposed through ACPI objects (refer to [2.5.3.1.8.3 \[ACPI Processor P-state Objects\]](#)). Software requests a core P-state change by writing a 3 bit index corresponding to the desired P-state number to [MSRC001\\_0062](#)[PstateCmd] of the appropriate core. For example, to request P3 for core 0 software would write 011b to core 0's [MSRC001\\_0062](#)[PstateCmd].

Boosted P-states may not be directly requested by software. Whenever software requests the P0 state on a processor that supports APM (i.e. writes 000b to [MSRC001\\_0062\[PstateCmd\]](#)), hardware dynamically places the core into the highest-performance P-state possible as determined by APM. See [2.5.9 \[Application Power Management \(APM\)\]](#).

Hardware sequences the frequency and voltage changes necessary to complete a P-state transition as specified by [2.5.3.1.5 \[Core P-state Transition Behavior\]](#) with no additional software interaction required. Hardware also coordinates frequency and voltage changes when differing P-state requests are made on cores that share a frequency or voltage plane. See [2.5.2 \[Frequency and Voltage Domain Dependencies\]](#) for details about hardware coordination.

**Table 10: Software P-state Control**

| D18F4x15C[NumBoostStates]=1 |                                |                           | D18F4x15C[NumBoostStates]=3 |                                |                           |
|-----------------------------|--------------------------------|---------------------------|-----------------------------|--------------------------------|---------------------------|
| P-state Name                | Index Used for Requests/Status | Corresponding MSR Address | P-state Name                | Index Used for Requests/Status | Corresponding MSR Address |
| Pb0                         | n/a                            | MSRC001_0064              | Pb0                         | n/a                            | MSRC001_0064              |
| P0                          | 0                              | MSRC001_0065              | Pb1                         | n/a                            | MSRC001_0065              |
| P1                          | 1                              | MSRC001_0066              | Pb2                         | n/a                            | MSRC001_0066              |
| P2                          | 2                              | MSRC001_0067              | P0                          | 0                              | MSRC001_0067              |
| P3                          | 3                              | MSRC001_0068              | P1                          | 1                              | MSRC001_0068              |
| P4                          | 4                              | MSRC001_0069              | P2                          | 2                              | MSRC001_0069              |
| P5                          | 5                              | MSRC001_006A              | P3                          | 3                              | MSRC001_006A              |
| P6                          | 6                              | MSRC001_006B              | P4                          | 4                              | MSRC001_006B              |

Hardware controls the VID for each voltage domain according to the highest requirement of the frequency domain(s) on each plane. For example, the VID for a 4 compute unit dual-plane system must be maintained at the highest level required for all 4 frequency domains. The number of frequency domains in a voltage domain is package/platform specific. Refer to [2.5.3.1.5 \[Core P-state Transition Behavior\]](#) for details on hardware P-state voltage control. [2.5.2.3 \[BIOS Requirements for Power Plane Initialization\]](#) specifies the processor initialization requirements for voltage plane control.

### 2.5.3.1.3 Core P-state Visibility

[MSRC001\\_0063\[CurPstate\]](#) reflects the current non-boosted P-state number for each compute unit. For example, if [MSRC001\\_0063\[CurPstate\]](#)=010b on compute unit 1, then compute unit 1 is in the P2 state. If a compute unit is in a boosted P-state, [MSRC001\\_0063\[CurPstate\]](#) reads back as 0.

The voltage on a compute unit may not correspond to the VID code specified by the current P-state of the compute unit due to voltage plane dependencies. See [2.5.2 \[Frequency and Voltage Domain Dependencies\]](#). If a compute unit is in the P0 state (i.e. if [MSRC001\\_0063\[CurPstate\]](#)=0), the frequency of the compute unit could be the frequency specified by P0 or any boosted P-state. To determine the frequency of a compute unit, see [2.5.3.3 \[Effective Frequency\]](#).

### 2.5.3.1.4 Core P-state Limits

Core P-states may be limited to lower-performance values under certain conditions, including:

- HTC. See [D18F3x64\[HtcPstateLimit\]](#).
- Software. See [D18F3x68\[SwPstateLimit\]](#).
- Core Performance Boost. See [2.5.9 \[Application Power Management \(APM\)\]](#).

- PROCHOT\_L assertion. See [2.10.3.1 \[PROCHOT\\_L and Hardware Thermal Control \(HTC\)\]](#).
- SMU. See [D18F4x13C\[SmuPstateLimit\]](#).

P-state limits are applied to all cores on the processor. The current P-state limit is provided in [MSRC001\\_0061\[CurPstateLimit\]](#). Changes to the [MSRC001\\_0061\[CurPstateLimit\]](#) can be programmed to trigger interrupts through [D18F3x64\[Ps1ApicLoEn, Ps1ApicHiEn\]](#). In addition, the maximum P-state value, regardless of the source, is limited as specified in [MSRC001\\_0061\[PstateMaxVal\]](#).

### 2.5.3.1.5 Core P-state Transition Behavior

The following rules specify how P-states changes function and interact with other system or processor states:

- If the P-state number is increasing (the compute unit is moving to a lower-performance state), then the COF is changed first, followed by the VID change. If the P-state number is decreasing, then the VID is changed first followed by the COF.
- When the processor initiates a VID change that increases voltage for a voltage domain, no new voltage or frequency changes occur until [D18F3xD8\[VSRampSlamTime\]](#) has expired, regardless of whether any new requests are received. When the processor initiates a VID change that decreases voltage for a voltage domain, new voltage or frequency changes are allowed to occur immediately.
  - This is true regardless of whether the frequency or voltages changes occur as a result of P-state or C-state changes.
- If multiple commands are issued that affect the P-state of a domain prior to when the processor initiates the change of the P-state of that domain, then the processor operates on the last one issued.
- Once a P-state change starts, the P-state state machine (PSSM) continues through completion unless interrupted by a PWROK deassertion. If multiple P-state changes are requested concurrently, the PSSM may group the associated VID changes separately from the associated COF changes.
- Behavior during RESET\_L assertions:
  - All cores are transitioned to C0.
  - VDD VID is transitioned to HWP0 VID. See [MSRC001\\_0064\[CpuVid\]](#).
  - If there is no P-state transition activity, then the compute units and NB remain in the current P-state. If there is an altvid applied:
  - If a RESET\_L assertion interrupts a P-state transition, then the COF remains in it's current state at the time RESET\_L is asserted (either the value of the old or the new P-state). BIOS is required to transition to valid COF and VID settings after a warm reset according to the sequence defined in [2.5.3.1.8 \[BIOS COF and VID Requirements After Warm Reset\]](#).
  - After a warm reset [MSRC001\\_0063 \[P-state Status\]](#) is consistent with [MSRC001\\_0071\[CurPstate\]](#). [MSRC001\\_0062 \[P-state Control\]](#) may not be consistent with [MSRC001\\_0071\[CurPstate\]](#).
- The OS controls the P-state through [MSRC001\\_0062 \[P-state Control\]](#), independent of P-state limits described in [D18F3x64\[HtcPstateLimit\]](#), [D18F3x68\[SwPstateLimit\]](#), and [D18F3xC4 \[SBI P-state Limit\]](#). P-state limits interact with OS-directed P-state transitions as follows:
  - Of all the active P-state limits, the one that represents the lowest-performance P-state number, at any given time, is treated as an upper limit on performance.
  - As the limit becomes active or inactive, or if it changes, the P-state for each compute unit is placed in either the last OS-requested P-state or the new limit P-state, whichever is a lower performance P-state number.
    - If the resulting P-state number exceeds [MSRC001\\_0061\[PstateMaxVal\]](#), regardless of whether it is a limit or OS-requested, then the PstateMaxVal is used instead.

### 2.5.3.1.6 BIOS Requirements for Core P-state Initialization and Transitions

1. Check that [CPUID Fn8000\\_0007\\_EDX\[HwPstate\]](#)=1. If not, P-states are not supported, no P-state related

- ACPI objects should be generated, and BIOS must skip the rest of these steps.
2. Complete the [2.5.2.3 \[BIOS Requirements for Power Plane Initialization\]](#).
  3. Ensure the following fields are configured to their BIOS recommendations:
    - [D18F3xA0](#)[PllLockTime].
    - [D18F3xD4](#)[PowerStepUp, PowerStepDown].
  4. Transition all cores to the minimum performance P-state using the algorithm detailed in [2.5.3.1.8.2 \[Core Minimum P-state Transition Sequence After Warm Reset\]](#).
  5. Complete the [2.5.4.1.2.1 \[NB P-state COF and VID Synchronization After Warm Reset\]](#). All cores on a processor must be in the minimum performance P-state prior to executing this sequence.
  6. Complete the [2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\]](#).
  7. Perform the following steps in any order:
    - A. Enable [2.5.9 \[Application Power Management \(APM\)\]](#) as follows:
      - Ensure the following fields are configured to their BIOS recommendations:
        - [D18F4x110](#)[CSampleTimer].
        - [D18F4x15C](#)[ApmMasterEn].
        - [D18F5xE0](#)[RunAvgRange].
      - If [D18F4x15C](#)[NumBoostStates] != 0, program [D18F4x15C](#)[BoostSrc] = 1.
    - B. Transition all cores to the maximum performance P-state by writing 0 to [MSRC001\\_0062](#)[PstateCmd]. This is done to enable faster boot times.
    - C. Create ACPI objects if necessary:
      - Determine the valid set of P-states as indicated by [MSRC001\\_00\[6B:64\]](#)[PstateEn].
      - If P-states are not supported, as indicated by only one enabled selection in [MSRC001\\_00\[6B:64\]](#)[PstateEn], then BIOS must not generate ACPI-defined P-state objects described in [2.5.3.1.8.3 \[ACPI Processor P-state Objects\]](#). Otherwise, the ACPI objects should be generated to enable P-state support.
    - D. Configure the COF and VID for each processor appropriately based on the sequence described in [2.5.4.1.2 \[BIOS NB P-state Configuration\]](#).
  8. Configure PSIX\_L. Refer to [2.5.1.3.1 \[PSIX\\_L Bit\]](#) for additional details.

### 2.5.3.1.7 Processor-Systemboard Power Delivery Compatibility Check

BIOS must disable processor P-states that require higher power delivery than the systemboard can support. This power delivery compatibility check is designed to prevent system failures caused by exceeding the power delivery capability of the systemboard for the power plane(s) that contain the core(s). Refer to [2.5.1 \[Processor Power Planes And Voltage Control\]](#) for power plane definitions and configuration information. BIOS can optionally notify the user if P-states are detected that exceed the systemboard power delivery capability. Modifications to [MSRC001\\_00\[6B:64\]](#) [P-state [7:0]] must be applied equally to all cores on the same node. This check does not ensure functionality for all package/socket compatible processor/systemboard combinations.

[MSRC001\\_00\[6B:64\]](#)[PstateEn] must be set to 0 for any P-state MSR where PstateEn=1 and the processor current requirement (ProcIddMax), defined by the following equation, is greater than the systemboard current delivery capability. ProcIddMax is reported in amps per core power plane.

$$\text{ProcIddMax} = \text{MSRC001\_00[6B:64]}[\text{IddValue}] \text{ current} * 1/10^{\text{MSRC001\_00[6B:64]}[\text{IddDiv}]} * (\text{D18F5x84}[\text{CmpCap}] + 1) * 1/2^{\text{D18F3xD8}[\text{PwrPlanes}]}$$

The power delivery check should be applied starting with hardware P0 and continue with increasing P-state indexes (1, 2, 3, and 4) for all enabled P-states. Once a compatible P-state is found using the ProcIddMax equation the check is complete. All processor P-states with higher indexes are defined to be lower power and performance, and are therefore compatible with the systemboard.

Example:

- MSRC001\_0065[IddValue] = 32d
- MSRC001\_0065[IddDiv] = 0d
- D18F5x84[CmpCap] = 1d
- ProcIddMax = 32 \* 1 \* 2 \* 1 = 64A per plane

The systemboard must be able to supply  $\geq 64A$  for the unified core power plane in order to support P1 for this processor. If the systemboard current delivery capability is  $< 64A$  per plane then BIOS must set MSRC001\_0065[PstateEn]=0 for all cores on this node, and continue by checking P2 in the same fashion.

If no P-states are disabled while performing the power delivery compatibility check then BIOS does not need to take any action.

If at least one P-state is disabled by performing the power delivery compatibility check and at least one P-state remains enabled, then BIOS must perform the following steps:

1. If the P-state pointed to by MSRC001\_0063[CurPstate] is disabled by the power delivery compatibility check, then BIOS must request a transition to an enabled P-state using MSRC001\_0062[PstateCmd] and wait for MSRC001\_0063[CurPstate] to reflect the new value.
2. Copy the contents of the enabled P-state MSR (MSRC001\_00[6B:64]) to the highest performance P-state locations. E.g. if P0 and P1 are disabled by the power delivery compatibility check and P2 - P4 remain enabled, then the contents of P2 - P4 should be copied to P0 - P2 and P3 and P4 should be disabled (PstateEn=0). This step uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering].
3. Request a P-state transition to the P-state MSR containing the COF/VID values currently applied. E.g. If MSRC001\_0063[CurPstate]=100b and P4 P-state MSR information is copied to P2 in step 2, then BIOS should write 010b to MSRC001\_0062[PstateCmd] and wait for MSRC001\_0063[CurPstate] to reflect the new value.
4. If a subset of boosted P-states are disabled, then copy the contents of the P-state MSR pointed to by the highest performance boosted P-state that is enabled to the P-state MSRs pointed to by the boosted P-states that are disabled.
5. If all boosted P-states are disabled, then program D18F4x15C[BoostSrc]=0.
6. Adjust the following P-state parameters affected by the P-state MSR copy by subtracting the number of software P-states that are disabled by the power delivery compatibility check. This calculation should not wrap, but saturate at 0. E.g. if P0 and P1 are disabled, then each of the following register fields should have 2 subtracted from them:
  - D18F3x64[HtcPstateLimit]
  - D18F3x68[SwPstateLimit]
  - D18F3xDC[HwPstateMaxVal]

If any node has all P-states disabled after performing the power delivery compatibility check, then BIOS must perform the following steps. This does not ensure operation and BIOS should notify the user of the incompatibility between the processor and systemboard if possible.

1. If MSRC001\_0063[CurPstate] != MSRC001\_0061[PstateMaxVal], then write MSRC001\_0061[PstateMaxVal] to MSRC001\_0062[PstateCmd] and wait for MSRC001\_0063[CurPstate] to reflect the new value.
2. If MSRC001\_0061[PstateMaxVal] != 000b copy the contents of the P-state MSR pointed to by MSRC001\_0061[PstateMaxVal] to MSRC001\_0064 and set MSRC001\_0064[PstateEn]; Write 000b to MSRC001\_0062[PstateCmd] and wait for MSRC001\_0063[CurPstate] to reflect the new value. This step uses software P-state numbering. See 2.5.3.1.1.1 [Software P-state Numbering].
3. Adjust the following fields to 000b.
  - D18F3x64[HtcPstateLimit]
  - D18F3x68[SwPstateLimit]

- [D18F3xDC\[HwPstateMaxVal\]](#)
4. Program [D18F4x15C\[BoostSrc\]=0](#).

### 2.5.3.1.8 BIOS COF and VID Requirements After Warm Reset

Warm reset is asynchronous and can interrupt P-state transitions leaving the processor in a VID state that does not correspond to [MSRC001\\_0063\[CurPstate\]](#) on any core. The processor frequency after warm reset corresponds to [MSRC001\\_0063\[CurPstate\]](#). See [2.5.3.1.5 \[Core P-state Transition Behavior\]](#) for P-state transition behavior when RESET\_L is asserted. BIOS is required to transition the processor to valid COF and VID settings corresponding to an enabled P-state following warm reset. The cores may be transitioned to either the maximum or minimum P-state COF and VID settings using the sequences defined in [2.5.3.1.8.1 \[Core Maximum P-state Transition Sequence After Warm Reset\]](#) and [2.5.3.1.8.2 \[Core Minimum P-state Transition Sequence After Warm Reset\]](#). Transitioning to the minimum P-state after warm reset is recommended to prevent undesired system behavior if a warm reset occurs before the [2.5.3.1.7 \[Processor-Systemboard Power Delivery Compatibility Check\]](#) is complete. BIOS must also transition NB COF and VID settings after warm reset for processors that support NB P-states (as indicated by NbDid=1 in any of [MSRC001\\_00\[6B:64\] \[P-state \[7:0\]\]](#)) using the sequence defined in [2.5.4.1.2.1 \[NB P-state COF and VID Synchronization After Warm Reset\]](#). BIOS is not required to manipulate NB COF and VID settings following warm reset if the warm reset was issued by BIOS to update [D18F5x16\[C:0\]\[NbFid\]](#).

#### 2.5.3.1.8.1 Core Maximum P-state Transition Sequence After Warm Reset

1. If [MSRC001\\_0071\[CurPstate\] = D18F3xDC\[HwPstateMaxVal\]](#), then skip step 3 for that core.
2. Write [MSRC001\\_0061\[PstateMaxVal\]](#) to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor. This step is required to ensure VDD is set to a non-boosted P-state voltage level since no cores should be in boost at this point. This step is not required for [2.5.3.1.8.2 \[Core Minimum P-state Transition Sequence After Warm Reset\]](#) since P-state down transitions are not gated by a boost voltage on VDD. See [2.5.3.1.5 \[Core P-state Transition Behavior\]](#).
3. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\] = \[CpuFid, CpuDid\]](#) from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC\[HwPstateMaxVal\]](#).
4. Wait for [MSRC001\\_0071\[CurCpuVid\] = \[CurCpuVid\]](#) from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC\[HwPstateMaxVal\]](#).
5. All previous steps must be completed on all cores prior to continuing the sequence since a compute unit transitions to the highest performance P-state requested on either core.
6. Write 0 to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.
7. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\] = \[CpuFid, CpuDid\]](#) from [MSRC001\\_00\[6B:64\]](#) indexed by [MSRC001\\_0071\[CurPstateLimit\]](#). The check against [MSRC001\\_0071\[CurPstateLimit\]](#) is required since [MSRC001\\_0071\[CurPstateLimit\]](#) affects the resultant P-state.
8. If [MSRC001\\_0071\[CurPstateLimit\] != D18F3xDC\[HwPstateMaxVal\]](#), wait for [MSRC001\\_0071\[CurCpuVid\] = \[CpuVid\]](#) from [MSRC001\\_00\[6B:64\]](#) indexed by [MSRC001\\_0071\[CurPstateLimit\]](#). See [2.5.3.1.8.2 \[Core Minimum P-state Transition Sequence After Warm Reset\]](#).
9. Wait for [MSRC001\\_0063\[CurPstate\] = MSRC001\\_0061\[CurPstateLimit\]](#).

#### 2.5.3.1.8.2 Core Minimum P-state Transition Sequence After Warm Reset

1. If [MSRC001\\_0071\[CurPstate\] = MSRC001\\_0071\[CurPstateLimit\]](#), then skip step 3 for that core.
2. Write 0 to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.
3. Wait for [MSRC001\\_0071\[CurCpuFid, CurCpuDid\] = \[CpuFid, CpuDid\]](#) from [MSRC001\\_00\[6B:64\]](#) indexed by [MSRC001\\_0071\[CurPstateLimit\]](#).
4. Write [MSRC001\\_0061\[PstateMaxVal\]](#) to [MSRC001\\_0062\[PstateCmd\]](#) on all cores in the processor.

5. Wait for [MSRC001\\_0071](#)[CurCpuFid, CurCpuDid] = [CpuFid, CpuDid] from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC](#)[HwPstateMaxVal].
6. If [MSRC001\\_0071](#)[CurPstateLimit] != [MSRC001\\_0071](#)[CurPstate], wait for [MSRC001\\_0071](#)[CurCpuVid] = [CpuVid] from [MSRC001\\_00\[6B:64\]](#) indexed by [D18F3xDC](#)[HwPstateMaxVal]. If [MSRC001\\_0071](#)[CurPstateLimit] = [MSRC001\\_0071](#)[CurPstate], do not perform a voltage check. On multi-node processors, there is a corner case where all core frequencies are in PstateMaxVal, but the voltage may not be.
7. Wait for [MSRC001\\_0063](#)[CurPstate] = [MSRC001\\_0062](#)[PstateCmd].

### 2.5.3.1.8.3 ACPI Processor P-state Objects

Processor performance control is implemented through the `_PCT`, `_PSS` and `_PSD` objects in ACPI 2.0 and later revisions. The presence of these objects indicates to the OS that the platform and processor are capable of supporting multiple performance states. Processor performance states are not supported with ACPI 1.0b. BIOS must provide the `_PCT`, `_PSS`, and `_PSD` objects, and define other ACPI parameters to support operating systems that provide native support for processor P-state transitions.

The following rules apply to BIOS generated ACPI objects in multi-core systems. Refer to the appropriate ACPI specification for additional details:

- All cores must expose the same number of performance states to the OS.
- The respective performance states displayed to the OS for each core must have identical performance and power-consumption parameters (e.g. P0 on core 0 must have the same performance and power-consumptions parameters as P0 on core 1, P1 on core 0 must have the same parameters as P1 on core 1, however P0 can be different than P1).
- Performance state objects must be present under each processor object in the system.

#### 2.5.3.1.8.3.1 `_PCT` (Performance Control)

BIOS must declare the performance control object parameters as functional fixed hardware. This definition indicates the processor driver understands the architectural definition of the P-state interface associated with [CPUID Fn8000\\_0007\\_EDX](#)[HwPstate]=1.

- `Perf_Ctrl_Register` = Functional Fixed Hardware
- `Perf_Status_Register` = Functional Fixed Hardware

#### 2.5.3.1.8.3.2 `_PSS` (Performance Supported States)

A unique `_PSS` entry is created for each non-boosted P-state. The value contained in the `_PSS` Control field is written to [MSRC001\\_0062](#) [P-state Control] to request a P-state change to the CoreFreq of the associated `_PSS` object. The value contained in [MSRC001\\_0063](#) [P-state Status] can be used to identify the `_PSS` object of the current P-state request by equating [MSRC001\\_0063](#)[CurPstate] to the value of the Status field. See [2.5.3.1 \[Core P-states\]](#).

BIOS loops through each of [MSRC001\\_00\[6B:64\]](#) applying the following formulas to create the fields for the `_PSS` object for for each valid P-state (see [MSRC001\\_00\[6B:64\]](#)[PstateEn]). BIOS skips over any P-state MSRs that specify boost P-states (see [D18F4x15C](#)[NumBoostStates]).

- CoreFreq (MHz) = Calculated using the formula for [CoreCOF](#).
- Power (mW) = [MSRC001\\_00\[6B:64\]](#)[CpuVid] voltage \* [MSRC001\\_00\[6B:64\]](#)[IddValue] current \* 1000.
- TransitionLatency (us) and BusMasterLatency (us):

- If `MSRC001_00[6B:64][CpuFid]` is the same for all enabled P-states (see `MSRC001_00[6B:64][PstateEn]`) and all boosted P-states:
  - $\text{TransitionLatency} = \text{BusMasterLatency} = (15 \text{ steps} * \text{D18F3xD4}[\text{PowerStepDown}] \text{ time} * 1000 \text{ us/ns}) + (15 \text{ steps} * \text{D18F3xD4}[\text{PowerStepUp}] \text{ time} * 1000 \text{ us/ns})$
- Else if `MSRC001_00[6B:64][CpuFid]` is different for any enabled (see `MSRC001_00[6B:64][PstateEn]`) or boost P-states:
  - $\text{TransitionLatency} = \text{BusMasterLatency} = (15 \text{ steps} * \text{D18F3xD4}[\text{PowerStepDown}] \text{ time} * 1000 \text{ us/ns}) + \text{D18F3xA0}[\text{PllLockTime}] \text{ time} + (15 \text{ steps} * \text{D18F3xD4}[\text{PowerStepUp}] \text{ time} * 1000 \text{ us/ns})$
- Example:
  - `MSRC001_00[6B:64][CpuFid]` is not the same for all P-states
  - `D18F3xD4[PowerStepDown] = D18F3xD4[PowerStepUp] = 8h (50 ns/step)`
  - `D18F3xA0[PllLockTime] = 001b (2 us)`
  - $\text{TransitionLatency} = \text{BusMasterLatency} = (15 \text{ steps} * 50 \text{ ns/step} / 1000 \text{ us/ns}) + 2\text{us} + (15 \text{ steps} * 50 \text{ ns/step} / 1000 \text{ us/ns}) = 3.5 \text{ us (round up to 4 us)}$
- Control/Status:
  - The highest performance non-boosted P-state must have the `_PSS` control and status fields programmed to 0.
  - Any lower performance non-boosted P-states must have the `_PSS` control and status fields programmed in ascending order.

#### 2.5.3.1.8.3.3 `_PPC` (Performance Present Capabilities)

The `_PPC` object is optional. Refer to the ACPI specification for details on use and content.

#### 2.5.3.1.8.3.4 `_PSD` (P-state Dependency)

AMD recommends the ACPI 3.0 `_PSD` object be generated for each core as follows to cause the cores to transition between P-states independently:

- `NumberOfEntries = 5`.
- `Revision = 0`.
- `Domain = CPUID Fn0000_0001_EBX[LocalApicId[7:2]]`.
- `CoordType = FEh. (HW_ALL)`
- `NumProcessors = 4`. Indicates the P-state dependency for the number of cores within a compute unit.

#### 2.5.3.1.8.4 Fixed ACPI Description Table (FADT) Entries

Declare the following FADT entries:

- `PSTATE_CNT = 00h`.
- `DUTY_WIDTH = 00h`.

#### 2.5.3.1.8.5 XPSS (Microsoft® Extended PSS) Object

Some Microsoft® operating systems require an XPSS object to make P-state changes function properly. A BIOS that implements an XPSS object has special requirements for the `_PCT` object. See the Microsoft *Extended PSS ACPI Method Specification* for the detailed requirements to implement these objects.

### 2.5.3.2 Core C-states

C-states are processor power states. C0 is the operational state in which instructions are executed. All other C-states are low-power states in which instructions are not executed. When coming out of warm and cold reset,

the processor is transitioned to the C0 state.

### 2.5.3.2.1 C-state Names and Numbers

C-states are often referred to by an alphanumeric naming convention, C1, C2, C3, etc. The mapping between ACPI defined C-states and AMD specified C-states is not direct. AMD specified C-states are referred to as IO-based C-states. Up to three IO-based C-states are supported, IO-based C-state 0, 1, and 2. The IO-based C-state index corresponds to the offset added to [MSRC001\\_0073\[CstateAddr\]](#) to initiate a C-state request. See [2.5.3.2.2 \[C-state Request Interface\]](#). The actions taken by the processor when entering a low-power C-state are configured by software. See [2.5.3.2.3 \[C-state Actions\]](#) for information about AMD specific actions.

### 2.5.3.2.2 C-state Request Interface

C-states are dynamically requested by software and are exposed through ACPI objects (see [2.5.3.2.6 \[ACPI Processor C-state Objects\]](#)). C-states can be requested on a per-core basis. Software requests a C-state change in one of two ways:

- Reading from an IO address: The IO address must be the address specified by [MSRC001\\_0073\[CstateAddr\]](#) plus an offset of 0 through 7. The processor always returns 0 for this IO read. Offsets 2 through 7 result in an offset of 2. The IO read is trapped by core microcode and does not leave the processor.
- Executing the HLT instruction. This is equivalent to reading from the IO address specified by [D18F4x128\[HaltCstateIndex\]](#).

Microcode communicates the C-state request to the NB by writing to [D18F4x114\[CstateIndex\]](#). When software requests a C-state transition, hardware evaluates any frequency and voltage domain dependencies and determines which C-state actions to execute. See [2.5.2 \[Frequency and Voltage Domain Dependencies\]](#) and [2.5.3.2.3 \[C-state Actions\]](#).

### 2.5.3.2.3 C-state Actions

A core takes one of several different possible actions based upon a C-state change request from software. The C-state action fields are defined in [D18F4x11\[C:8\]](#).

#### 2.5.3.2.3.1 C-state Probes and Cache Flushing

If probes occur after a core enters a non-C0 state, and the caches are not flushed by hardware, the core clock may be ramped back up to the C0 frequency to service the probes, as specified by [D18F4x118/D18F4x11C\[CpuPrbEn\]](#).

If a core enters a non-C0 state and cache flush is enabled (see [D18F3xDC\[CacheFlushOnHaltCtl\]](#) and [D18F4x118/D18F4x11C\[CacheFlushEn\]](#)), a timer counts down for a programmable period of time as specified by [D18F3xDC\[CacheFlushOnHaltTmr\]](#) or [D18F4x118/D18F4x11C\[CacheFlushTmrSel\]](#). When the timer expires, the core flushes its L1 cache to L2 cache and the core clocks are ramped down to a divisor specified by [D18F3xDC\[CacheFlushOnHaltCtl\]](#). If the core is the last core within a CPC to enter CC6 (see [2.5.5.2.3.5 \[XC6 State\]](#)), then L2 cache is flushed to DRAM. The core checks for interrupts after each sector of the cache is flushed and exits the C-state if an interrupt occurs. The timer is reset if the core exits the C-state for any reason. See [2.5.3.2.4.2 \[Cache Flush On Halt Saturation Counter\]](#).

As a core enters a non-C0 state, probes are blocked on all cores within a CPC until all probes to the CPC are drained. When all responses are returned from L2 cache, the core may enter non-C0 state. Once a core flushes its caches and performs the stpclk handshake with the L2I, probes are no longer sent to that core. This improves probing performance for cores that are in C0.

### 2.5.3.2.3.2 Core C1 (CC1) State

When a core enters the CC1 state, its clock ramps down to the frequency specified by [D18F4x118/D18F4x11C](#)[ClkDivisorCstAct].

### 2.5.3.2.3.3 Core C6 (CC6) State

A core can gate off power to its internal logic when it enters any non-C0 state. This power gated state is known as CC6. In order to enter CC6, hardware first enters CC1 then checks [D18F4x118/D18F4x11C](#)[PwrGateEnCstAct]. Power gating reduces the amount of power consumed by the core. VDD voltage is not reduced when a core is in CC6. The following sequence occurs when a core enters the CC6 state:

8. If [MSRC001\\_10A0](#)[CacheC6StateDis]=0, Internal core state is saved to L1 cache (microcode). Else, internal core state is saved to DRAM.
9. L1 cache is flushed to L2 cache (microcode). See [2.5.3.2.3.1 \[C-state Probes and Cache Flushing\]](#).
10. Power is removed from the core and the core PLL/voltage regulator is powered down as specified by [D18F5x128](#)[CC6PwrDwnRegEn and CC6PwrDwnVcoEn].

All of the following must be true in order for a core to be placed into CC6:

- [D18F4x118/D18F4x11C](#)[CacheFlushEn]=1 for the corresponding C-state action field.
- [D18F4x118/D18F4x11C](#)[CacheFlushTmrSel] != 11b for the corresponding C-state action field.
- [D18F4x118/D18F4x11C](#)[PwrGateEnCstAct]=1 for the corresponding C-state action field.
- [D18F2x118](#)[CC6SaveEn]=1.
- [D18F2x118](#)[LockDramCfg]=1 or [D18F3x12C](#)[OverrideLockDramCfg]=1.
- The CC6 storage area in DRAM is configured. See [2.9.11 \[DRAM CC6/PC6 Storage\]](#).

The events which cause a core to exit the CC6 state are specified in [2.5.3.2.5 \[Exiting C-states\]](#). When a core exits the CC6 state, it executes the following sequence:

If a warm reset occurs while a core is in CC6, all MCA registers in the core shown in [Table 65](#) are cleared to 0. See [2.14.1 \[Machine Check Architecture\]](#). Since the core was in CC6, the core was not the cause of the warm reset. As a result, no information pertinent to the reset is lost. Correctable error information logged prior to CC6 entry may be lost, but this is not critical to system operation.

The time required to enter and exit CC6 is directly proportional to the core P-state frequency. Slower core frequencies require longer entry and exit times. Latency issues may occur with core P-state frequencies less than 800MHz.

### 2.5.3.2.3.4 Package C6 (PC6) State

When all cores enter a non-C0 state, VDD can be reduced to a non-operational voltage that does not retain core state. This state is known as PC6 and reduces the amount of static and dynamic power consumed by all cores. The following actions are taken by hardware prior to PC6 entry:

1. If [D18F3xA8](#)[CC6PopDownEn]=1 and [MSRC001\\_0071](#)[CurPstate] < [D18F3xA8](#)[PopDownPstate], transition the core P-state to [D18F3xA8](#)[PopDownPstate].
2. If [MSRC001\\_10A0](#)[CacheC6StateDis]=0, For all cores not in CC6, internal core state is saved to L1 cache (microcode). Else, internal core state is saved to DRAM.
3. For all cores not in CC6, L1 cache is flushed to L2 cache (microcode). See [2.5.3.2.3.1 \[C-state Probes and Cache Flushing\]](#).
4. VDD is transitioned to the VID specified by [D18F5x128](#)[PC6Vid].

5. If the core PLLs are not powered down during CC6 entry (see 2.5.3.2.3.3 [Core C6 (CC6) State]), then they are powered down as specified by D18F5x128[PC6PwrDwnRegEn].

All of the following must be true on all cores in order for a package to be placed into PC6:

- D18F4x118/D18F4x11C[CacheFlushEn]=1 for the corresponding C-state action field
- D18F4x118/D18F4x11C[CacheFlushTmrSel] != 11b for the corresponding C-state action field.
- D18F4x118/D18F4x11C[PwrOffEnCstAct]=1 for the corresponding C-state action field.
- D18F2x118[CC6SaveEn]=1.
- D18F2x118[LockDramCfg]=1 or D18F3x12C[OverrideLockDramCfg]=1.

#### 2.5.3.2.4 C-state Request Monitors

Deeper C-states have higher entry and exit latencies but provide greater power savings than shallower C-states. To help balance the performance and power needs of the system, the processor can limit access to specific C-states in certain scenarios.

##### 2.5.3.2.4.1 FCH Messaging

The FCH can be notified when the processor transitions package C-states. See the following:

- D18F4x128[CstateMsgDis].
- D18F5x178[CstateFusionDis].

##### 2.5.3.2.4.2 Cache Flush On Halt Saturation Counter

A cache flush success monitor tracks the success rate of cache flush timer expirations relative to the core exiting a C-state. Based on the success rate, caches may be flushed immediately without waiting for the cache flush timer to expire. See D18F4x130[CacheFlushSuccessMonitor] and D18F4x128[CacheFlushSucMonThreshold]. When the core resumes normal execution, the caches refill as normal.

##### 2.5.3.2.5 Exiting C-states

The following events may cause the processor to exit a non-C0 C-state and return to C0:

- INTR
- NMI
- SMI
- INIT
- RESET\_L assertion

If an INTR is received while a core is in a non-C0 C-state, the state of EFLAGS[IF] and the mechanism used to enter the non-C0 C-state determine the actions taken by the processor.

- Entry via HLT, EFLAGS[IF]==0: The interrupt does not wake up the core.
- Entry via HLT, EFLAGS[IF]==1: The interrupt wakes the core and the core begins execution at the interrupt service routine.
- Entry via IO read, EFLAGS[IF]==0: The interrupt wakes the core and the core begins execution at the instruction after the IN instruction that was used to enter the non-C0 C-state.
- Entry via IO read, EFLAGS[IF]==1: The interrupt wakes the core and the core begins execution at the interrupt service routine.

### 2.5.3.2.6 ACPI Processor C-state Objects

Processor power control is implemented through the `_CST` object in ACPI 2.0 and later revisions. The presence of the `_CST` object indicates to the OS that the platform and processor are capable of supporting multiple power states. BIOS must provide the `_CST` object and define other ACPI parameters to support operating systems that provide native support for processor C-state transitions. See 2.5.3.2.6.1 [`_CST`].

The `_CST` object is not supported with ACPI 1.0b. BIOS should provide FADT entries to support operating systems that are not compatible with ACPI 2.0 and later revisions. See 2.5.3.2.6.2 [`_CRS`].

#### 2.5.3.2.6.1 `_CST`

The `_CST` object should be generated for each core as follows:

- Count = 1.
- Register = `MSRC001_0073`[CstateAddr] + 1.
- Type = 2.
- Latency = 400. From CC6 Latency Calculations.
- Power = 0. This field is set to 0 since it's not used by Linux, Win7, or Vista.

#### 2.5.3.2.6.2 `_CRS`

BIOS must declare in the root host bridge `_CRS` object that the IO address range from `MSRC001_0073`[CstateAddr] to `MSRC001_0073`[CstateAddr]+7 is consumed by the host bridge.

#### 2.5.3.2.6.3 Fixed ACPI Description Table (FADT) Entries

Declare the following FADT entries:

- `P_LVL2_LAT` = 100. BOZO: This value needs to be updated once the latency equation is finalized.
- `P_LVL3_LAT` = 1001.
- `FLAGS.PROC_C1` = 1.
- `FLAGS.P_LVL2_UP` = 1.

Declare the following `P_BLK` entries:

- `P_LVL2` = `MSRC001_0073`[CstateAddr] + 1.
- `P_LVL3` = 0.

BIOS must declare the `PSTATE_CNT` entry as 00h.

#### 2.5.3.2.7 BIOS Requirements for Initialization

1. Initialize `MSRC001_0073`[CstateAddr] with an available IO address. See 2.5.3.2.6.2 [`_CRS`].
2. Initialize `D18F4x11`[C:8].
3. Generate ACPI objects as described in 2.5.3.2.6 [`ACPI Processor C-state Objects`].

### 2.5.3.3 Effective Frequency

The effective frequency interface allows software to discern the average, or effective, frequency of a given core over a configurable window of time. This provides software a measure of actual performance rather than forcing software to assume the current frequency of the core is the frequency of the last P-state requested. This can be useful when the P-state is limited by:

- HTC
- `D18F3x68`[SwPstateLimit]

- SBI
- CPB

The following procedure calculates effective frequency using [MSR0000\\_00E7](#) [Max Performance Frequency Clock Count (MPERF)] and [MSR0000\\_00E8](#) [Actual Performance Frequency Clock Count (APERF)]:

1. At some point in time, write 0 to both MSRs.
2. At some later point in time, read both MSRs.
3. Effective frequency = (value read from [MSR0000\\_00E8](#) / value read from [MSR0000\\_00E7](#)) \* P0 frequency using software P-state numbering.

Additional notes:

- The amount of time that elapses between steps 1 and 2 is determined by software.
- It is software's responsibility to disable interrupts or any other events that may occur in between the write of [MSR0000\\_00E7](#) and the write of [MSR0000\\_00E8](#) in step 1 or between the read of [MSR0000\\_00E7](#) and the read of [MSR0000\\_00E8](#) in step 2.
- The behavior of [MSR0000\\_00E7](#) and [MSR0000\\_00E8](#) may be modified by [MSRC001\\_0015](#)[EffFreqCntMwait].
- The effective frequency interface provides +/- 50MHz accuracy if the following constraints are met:
- Effective frequency is read at most one time per millisecond.
- When reading or writing [MSR0000\\_00E7](#) and [MSR0000\\_00E8](#) software executes only MOV instructions, and no more than 3 MOV instructions, between the two RDMSR or WRMSR instructions.
- [MSR0000\\_00E7](#) and [MSR0000\\_00E8](#) are invalid if an overflow occurs. Intel defines each counter to reset to 0 on overflow. AMD counters simply wrap.

## 2.5.4 NB Power Management

### 2.5.4.1 NB P-states

The processor supports up to four NB P-states (NBP0 through NBP3), specified in [D18F5x16\[C:0\]](#). Each NB P-state consists of the following:

- Enable: [D18F5x16\[C:0\]\[NbPstateEn\]](#).
- NCLK frequency: [D18F5x16\[C:0\]\[NbFid, NbDid\]](#).
- VDDNB voltage: [D18F5x16\[C:0\]\[NbVid\]](#).
- Memory P-state: [D18F5x16\[C:0\]\[MemPstate\]](#). See 2.5.7.1 [Memory P-states].

Out of cold reset, the NB P-state is specified by [D18F5x174](#)[StartupNbPstate] and [D18F3xA0](#)[CofVidProg]. The current NB P-state is specified by [D18F5x174](#)[CurNbFid, CurNbDid, CurNbVid].

Although four NB P-states are defined, only two NB P-states are used at any given time, specified by [D18F5x170](#)[NbPstateHi, NbPstateLo]. See 2.5.6.1.5.2 [NB P-state Pointer Configuration].

#### 2.5.4.1.1 NB P-state Transitions

Hardware selects whether to use the high or low NB P-state based on several criteria as follows:

- Core P-state:
  - [MSRC001\\_00](#)[6B:64][NbPstate].
  - [D18F5x170](#)[NbPstateThreshold].
- GPU activity (current SCLK DPM state):

- The GPU driver selects levels of GPU activity that force the NB P-state to either the high or low state or allow either NB P-state.
- Hysteresis timer:
  - [D18F5x170](#)[NbPstateHiRes, NbPstateLoRes].
- The following configuration registers:
  - [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateGnbSlowDis].
  - [MSRC001\\_0071](#)[NbPstateDis].

Once the UNB determines that an NB P-state transition is necessary, the UNB executes the following sequence:

1. If transitioning from the low NB P-state to the high NB P-state, transition VDDNB voltage.
2. If the GPU is enabled as specified by [D18F5x178](#)[SwGfxDis], wait for display buffer to fill.
3. Quiesce all active cores.
4. If the internal GPU is enabled as specified by [D18F5x178](#)[SwGfxDis], wait for display buffer to fill (see [D18F5x178](#)[Dis2ndGnbAllowPsWait]).
5. Stop memory traffic and place DRAM into self-refresh.
6. Transition NCLK frequency.
7. Update NB P-state specific DRAM settings within hardware, see [D18F2x210\\_dct\[0\]\\_nbp\[3:0\]](#).
8. Take DRAM out of self-refresh and allow memory traffic.
9. Wake up cores.
10. If transitioning from the high NB P-state to the low NB P-state, transition VDDNB voltage.

#### 2.5.4.1.2 BIOS NB P-state Configuration

##### 2.5.4.1.2.1 NB P-state COF and VID Synchronization After Warm Reset

BIOS performs the following sequence on one core. This is done after any warm reset and before [2.9.7 \[DCT/DRAM Initialization and Resume\]](#). The sequence must always be performed to ensure the NB VID request matches the NB P-state request.

1. Temp1=[D18F5x170](#)[SwNbPstateLoDis].
2. Temp2=[D18F5x170](#)[NbPstateDisOnP0].
3. Temp3=[D18F5x170](#)[NbPstateThreshold].
4. Temp4=[D18F5x170](#)[NbPstateGnbSlowDis].
5. If [MSRC001\\_0070](#)[NbPstate]=0, go to step 6. If [MSRC001\\_0070](#)[NbPstate]=1, go to step 11.
6. Write 1 to [D18F5x170](#)[NbPstateGnbSlowDis].
7. Write 0 to [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateThreshold].
8. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateLo] and [D18F5x174](#)[CurNbFid, CurNbDid]=[NbFid, NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateLo].
9. Set [D18F5x170](#)[SwNbPstateLoDis]=1.
10. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateHi] and [D18F5x174](#)[CurNbFid, CurNbDid]=[NbFid, NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateHi]. Go to step 15.
11. Write 1 to [D18F5x170](#)[SwNbPstateLoDis].
12. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateHi] and [D18F5x174](#)[CurNbFid, CurNbDid]=[NbFid, NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateHi].
13. Write 0 to [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateThreshold].
14. Wait for [D18F5x174](#)[CurNbPstate] = [D18F5x170](#)[NbPstateLo] and [D18F5x174](#)[CurNbFid, CurNbDid]=[NbFid, NbDid] from [D18F5x16\[C:0\]](#) indexed by [D18F5x170](#)[NbPstateLo].
15. Set [D18F5x170](#)[SwNbPstateLoDis]=Temp1, [D18F5x170](#)[NbPstateDisOnP0]=Temp2, and [D18F5x170](#)[NbPstateThreshold]=Temp3, and [D18F5x170](#)[NbPstateGnbSlowDis]=Temp4.

### 2.5.4.1.2.2 NB P-state Transitions

During boot when [D18F5x174](#)[NbPstateDis]=0, BIOS forces the processor to the desired NB P-states using the following steps:

1. Save the values in [D18F5x170](#) for later restoration to unforce the NB P-state.
2. Set the desired NB P-state pointers, [D18F5x170](#)[NbPstateHi, NbPstateLo]. See [2.5.6.1.5.2 \[NB P-state Pointer Configuration\]](#).
3. Transition to the desired state as follows:
  - In order to transition to [D18F5x170](#)[NbPstateHi], program [D18F5x170](#) as follows:
    - SwNbPstateLoDis = 1.
    - Wait for [D18F5x174](#)[CurNbPstate] to equal NbPstateHi.
  - In order to transition to [D18F5x170](#)[NbPstateLo], program [D18F5x170](#) as follows:
    - SwNbPstateLoDis = NbPstateDisOnP0 = NbPstateThreshold = 0.
    - Wait for [D18F5x174](#)[CurNbPstate] to equal NbPstateLo.

BIOS performs the following to release the NB P-state force:

4. Release the NB P-state force by restoring initial [D18F5x170](#) values.
  - Restore the initial [D18F5x170](#)[SwNbPstateLoDis, NbPstateDisOnP0, NbPstateLo] values.
  - Restore the initial [D18F5x170](#)[NbPstateThreshold, NbPstateHi] values.

### 2.5.4.1.2.3 NB P-state Configuration for Runtime

Please see the SMU programming guide (see [1.2 \[Reference Documents\]](#)) for details.

### 2.5.4.2 NB C-states

NB C-states are package-level actions that occur only when all cores enter a non-C0 state (see [2.5.3.2 \[Core C-states\]](#)). See also [2.20.5.1 \[Trace Mode Active/Inactive\]](#). The NB C-state actions are:

- DRAM self-refresh (see [2.5.7.2 \[DRAM Self-Refresh\]](#)):
  - Enable bits: [D18F4x118/D18F4x11C](#)[SelfRefr] and [D18F5x128](#)[SelfRefrDis].
  - Entry requirements (all of the following must be true):
    - No outstanding GPU traffic or traffic from a link. (GPU->UNB traffic)
  - Exit conditions (any of the following must be true):
    - The local APIC timer expires. See [2.4.8.1 \[Local APIC\]](#).
    - New GPU traffic or traffic from a link. (GPU->UNB traffic)
    - A P-state limit update (see [2.5.3.1.4 \[Core P-state Limits\]](#)) causes the most restrictive P-state limit to become a higher number than the current P-state for any core in CC1.
- NB clock gating:
  - Enable bits: [D18F4x118/D18F4x11C](#)[NbClkGate] and [D18F5x128](#)[ClkGateDis].
  - Entry requirements:
    - No outstanding GPU traffic or traffic from a link.
  - Exit conditions (any of the following must be true):
    - The local APIC timer expires. See [2.4.8.1 \[Local APIC\]](#).
    - New GPU traffic or traffic from a link.
    - A P-state limit update (see [2.5.3.1.4 \[Core P-state Limits\]](#)) causes the most restrictive P-state limit to become a higher number than the current P-state for any core in CC1.

When entering NB C-states, the actions are taken in the following order:

1. DRAM self-refresh.
2. NB clock gating.

When exiting NB C-states, the actions are taken in the following order:

1. NB clock gating.
2. DRAM self-refresh.

## 2.5.5 Bandwidth Requirements

- The frequency relationship of  $(\text{core COF} / \text{NB COF}) \leq 6$  &  $(\text{core COF} / \text{NB COF}) \geq 1$  must be maintained for all supported P-state combinations. E.g., a core P0 COF of 4.0 GHz could not be combined with a NB P0 COF of 0.6 GHz; the NB P0 COF would have to be 0.8 GHz or greater; if the NB P0 COF is 1.2 GHz, then the NB P1 COF of 0.6 GHz may only be supported if the corresponding core P-state specify a COF of 3.0 GHz or less. This limit is only a bound for verification.
- All core P-states are required to be defined such that  $(\text{NB COF} / \text{core COF}) \leq 32$ , for all NB/core P-state combinations. E.g., if the NB COF is 4.8 GHz then the core COF must be no less than 150 MHz; support for an NB P-state that brings the NB COF down to 2.4 GHz would not change the core COF requirement, since all NB/core P-state combinations must meet this requirement.
- All core P-states must be defined such that **CoreCOF**  $\geq 600$  MHz.
- **NBCOF**  $\geq$  MEMCLK frequency.
- $400\text{MHz} \leq \text{NBCOF} \leq 1600\text{MHz}$ .
- **NBCOF**  $\leq 2 * \text{MEMCLK}$  frequency.

## 2.5.6 GPU and Root Complex Power Management

### 2.5.6.1 Dynamic Power Management (DPM)

The processor supports dynamic GPU frequency changes along with VDDNB voltage change requests, known as Dynamic Power Management (DPM). Once initialized, hardware dynamically monitors processor utilization and adjusts the frequencies and voltage based on that utilization. For DPM, higher numbered states represent higher performance and lower numbered states represent lower performance.

#### 2.5.6.1.1 Activity Monitors

The processor contains activity monitors which track the usage level of different processor subcomponents. A binary signal from each subcomponent is used to determine whether that subcomponent is busy. On each clock cycle, the activity monitor samples the signal from each unmasked subcomponent. If any given subcomponent reports that it is busy, an accumulator is incremented.

See [D0F0xBC\\_xC020\\_0110](#) and [D0F0xBC\\_xC0200118](#) for LCLK DPM activity monitor.

The output of the activity monitor is then used to determine whether the DPM state should be changed.

#### 2.5.6.1.2 SCLK DPM

SCLK DPM consists of up to 8 states. Any number of states up through 8 may be used and there is no requirement that the states be contiguous.

During runtime, SCLK DPM parameters are programmed by the graphics driver. To support the driver, BIOS creates a data structure in memory containing information about the processor. Please see your AMD

representative for more information.

### 2.5.6.1.3 LCLK DPM

LCLK DPM consists of up to 8 states. Any number of states up through 8 may be used and there is no requirement that the states be contiguous. Each state is made up of the following parameters.

- Valid bit: [D0F0xBC\\_x3FD\[8C:00:step14\]\[StateValid\]](#).
- Voltage change hysteresis threshold: [D0F0xBC\\_x3FD\[8C:00:step14\]\[LowVoltageReqThreshold\]](#).
- Divisor: [D0F0xBC\\_x3FD\[8C:00:step14\]\[LclkDivider\]](#).
- VID: [D0F0xBC\\_x3FD\[8C:00:step14\]\[VID\]](#).
  - See [2.5.2.2 \[Dependencies Between Subcomponents on VDDNB\]](#).
- State change hysteresis thresholds: [D0F0xBC\\_x3FD\[94:08:step14\]\[HysteresisUp, HysteresisDown\]](#).
- Activity thresholds: [D0F0xBC\\_x3FD\[9C:10:step14\]\[ActivityThreshold\]](#).
- Residency counter: See [D0F0xBC\\_x3FD\[94:08:step14\]\[ResidencyCounter\]](#).

LCLK DPM is enabled by setting [D0F0xBC\\_x3FDC8\[LclkDpmEn\]](#) to 1 and interrupting the SMU with Service Index 1Eh (see [2.12.1 \[Software Interrupts\]](#)). LCLK DPM voltage changes are enabled using [D0F0xBC\\_x3FDC8\[VoltageChgEn\]](#). When LCLK DPM is first enabled, the DPM state is transitioned to [D0F0xBC\\_x3FDC8\[LclkDpmBootState\]](#).

### 2.5.6.2 GPU and Root Complex Power Gating

Several subcomponents of the GPU and root complex can be power gated when not in use.

- **GPU:** GPU power gating is initialized and enabled by software (see [GpuEnabled](#) and [D0F0x7C\[ForceIntGfxDisable\]](#)). Once initialized and enabled, the GPU is power gated by hardware when inactive and is ungated by hardware when needed. When internal GPU is disabled by BIOS, BIOS is responsible for power gating the GPU. When internal GPU is disable via fusing, hardware power gates the GPU.
- **UVD:** UVD is power gated by software when not in use and is ungated by software when needed. UVD's internal state is not saved and UVD goes through an internal reset when power is restored.
- **GMC:** GMC power gating is initialized and enabled by software. Once initialized and enabled, GMC is power gated by hardware when inactive and is ungated by hardware when needed. GMC's state is saved internally. If the internal GPU is disabled, either by hardware (fusing) or by software, software is responsible for power gating GMC.
- **VCE:** VCE is power gated by software when not in use and is ungated by software when needed. VCE's internal state is not saved and VCE goes through an internal reset when power is restored.
- **DCE:** DCE is power gated by software when there is no display connected. DCE's internal state is not saved and DCE goes through an internal reset when power is restored.
- **PCIe:** The Gfx link core can be power gated when it is not in use. In addition, the individual phys on the TX and RX sides of each link can be power gated when the links are not connected. During POST and runtime, several software components inform the SMU whether the Gfx link core or the link phys are in use. Hardware dynamically power gates or ungates the Gfx link core and the link phys as needed.

## 2.5.7 DRAM Power Management

### 2.5.7.1 Memory P-states

The processor supports up to 2 memory P-states, M0 and M1. Each memory P-state consists of the following:

- MEMCLK frequency
- A set of frequency dependent DRAM timing and configuration registers

See 2.9 [DRAM Controllers (DCTs)] for DRAM technology specific information and requirements.

All valid memory P-states are associated with a specific NB P-state, as specified by [D18F5x16\[C:0\]\[MemPstate\]](#). When hardware transitionsto a new NB P-state, the memory P-state is transitioned to that specified by the new NB P-state.

Out of cold reset the current memory P-state is M0. The P-state value specified by [D18F5x16\[C:0\]\[MemPstate\]](#) of the NB P-state indexed by [D18F5x174\[StartupNbPstate\]](#) is invalid. Support for dynamic memory P-state changes is indicated by [D18F3xE8\[MemPstateCap\]=1](#) and one or more [D18F5x16\[C:0\]\[MemPstate\]=1](#); otherwise M0 is used by hardware for configuration purposes.

During boot, and if [D18F5x170\[MemPstateDis\]=0](#), the BIOS can disable memory P-states using the following steps:

1. Program [D18F5x170\[MemPstateDis\]=1](#).
2. Program [D18F5x16\[C:0\]\[MemPstate\]=0](#).

### 2.5.7.2 DRAM Self-Refresh

DRAM is placed into self-refresh on S3 entry (see 2.5.8.1.1 [ACPI Suspend to RAM State (S3)]). [D18F5x178\[AllowSelfRefrS3Dis\]](#) controls whether the NB waits for the GPU to assert an internal AllowSelfRefresh signal before transitioning into self-refresh. [D18F5x178\[InbWakeS3Dis\]](#) controls whether the NB to GPU interface must be idle before this transition is started.

In addition to S3, DRAM is placed into self-refresh in S0 in the following two scenarios:

- NB P-state transitions (see 2.5.4.1 [NB P-states]).
- NB C-states (see 2.5.4.2 [NB C-states]).

The following requirements must be met before hardware places DRAM into self-refresh:

- No pending traffic.
- One of the following is true:
  - The GPU is idle and the internal display buffer is full as specified by [Bozo:GMMx63C\[McAllowStop\]](#).
  - The internal GPU is disabled.

Once the above requirements are met, the NB asserts an internal signal called PreSelfRefresh. In response, the GNB asserts an internal signal called AllowSelfRefresh when the DMIF region representing its own display is full or exceeds the high watermark (see BOZO2.5.9.3 [Stutter Mode]), and hardware places DRAM into self-refresh.

Early self-refresh occurs when DRAMs are placed in self-refresh before expiration of the cache flush timer. See [D18F4x118/D18F4x11C\[SelfRefrEarly\]](#) and [D18F5x128\[SelfRefrEarlyDis\]](#). If early self-refresh is

enabled, the DRAMs are taken out of self-refresh to perform the flush operation when the cache flush timer expires and then placed back into self-refresh.

The following are events that cause DRAM to transition out of self-refresh:

- Core transitioning to C0.
- Incoming request from any link or the GMC as indicated by the assertion of the internal signal InbWake.
- P-state limit update, only in the case when all cores are not in the power gated (CC6) state.

To save additional power, hardware always tristates MEMCLK when entering self-refresh.

### 2.5.7.3 Stutter Mode

DRAM is most commonly placed in self-refresh due to stutter mode when the internal GPU is in use. The display buffer in the GPU is a combination of a large buffer known as the DMIF (Display Memory Interface FIFO) and a smaller line buffer. The DMIF takes data originating from DRAM and sends it to the line buffer to draw to the screen. When the data level in the DMIF is full, DRAM is placed in self-refresh, and incoming DRAM requests are queued. As the DMIF drains, it eventually falls below a predefined watermark level, at which point hardware pulls DRAM out of self-refresh and services all the requests in the queue. Once all the requests are complete and the DMIF is full again, a transition back into self-refresh occurs if the stutter mode conditions are still met.

#### 2.5.7.3.1 System BIOS Requirements for Stutter Mode Operation During POST

BIOS creates a data structure in memory containing information about the processor for use by the driver. Please see your AMD representative for more information.

### 2.5.7.4 EVENT\_L

EVENT\_L is a level sensitive input to the processor. When asserted, the actions specified by [D18F2xA4](#) are taken. EVENT\_L is generally asserted to indicate that a DRAM high temperature condition exists. The minimum assertion time for EVENT\_L is 15 ns. The minimum deassertion time for EVENT\_L is 15 ns.

- EVENT\_L is pulled to VDDIO on the motherboard.
- EVENT\_L is ignored while:
  - PWROK is de-asserted.
  - RESET\_L is asserted.
- BIOS must ensure that throttling is disabled (see [D18F2xA4](#)[CmdThrottleMode]) until DRAM training is complete.

See [2.9.12 \[DRAM On DIMM Thermal Management and Power Capping\]](#).

## 2.5.8 System Power Management

### 2.5.8.1 S-states

S-states are ACPI defined sleep states. S0 is the operational state. All other S-states are low-power states in which various voltage rails in the system may or may not be powered. See the ACPI specification for descriptions of each S-state. The only other S-state supported is S5.

#### 2.5.8.1.1 ACPI Suspend to RAM State (S3)

The processor supports the ACPI-defined S3 state. Software is responsible for restoring the state of the processor's registers when resuming from S3. All registers in the processor that BIOS initialized during the

initial boot must be restored. The method used to restore the registers is system specific.

During S3 entry, software is responsible for transitioning the processor to Memory Pstate0. See [2.5.7.1 \[Memory P-states\]](#).

During S3 entry, system memory enters self-refresh mode (see [2.5.7.2 \[DRAM Self-Refresh\]](#)). Software is responsible for bringing memory out of self-refresh mode when resuming from S3. To bring memory out of self-refresh mode. See [2.9.7 \[DCT/DRAM Initialization and Resume\]](#).

Many of the systemboard power planes for the processor are powered down during S3. Refer to the Electrical Data Sheet and the AMD Infrastructure Roadmap for the following:

- Power plane electrical requirements during S3.
- Power plane sequencing requirements on S3 entry and exit.
- System signal states for both inputs (e.g. PWROK and RESET\_L) and outputs (e.g. VID[\*], PSI\_L bit, THERMTRIP\_L, etc.) during S3.
- System signal sequencing requirements on S3 entry and exit.
- System management message sequencing on S3 entry and exit.

## 2.5.9 Application Power Management (APM)

Application Power Management (APM) allows the processor to deterministically provide maximum performance while remaining within the specified power delivery and removal envelope. APM dynamically monitors processor activity and generates an approximation of power consumption. If power consumption exceeds a defined power limit, a P-state limit is applied by APM hardware to reduce power consumption. APM ensures that average power consumption over a thermally significant time period remains at or below the defined power limit. This allows P-states to be defined with higher frequencies and voltages than could be used without APM.

### 2.5.9.1 Core Performance Boost (CPB)

These P-states are referred to as boosted P-states.

- Support for APM is specified by [CPUID Fn8000\\_0007\\_EDX\[CPB\]](#).
- APM is enabled if all of the following conditions are true:
  - [MSRC001\\_0015\[CpbDis\]](#) = 0 for all cores.
  - [D18F4x15C\[ApmMasterEn\]](#) = 1.
  - [D18F4x15C\[BoostSrc\]](#) = 01b.
  - [D18F4x15C\[NumBoostStates\]](#) != 0.
- APM can be dynamically enabled and disabled through [MSRC001\\_0015\[CpbDis\]](#). If core performance boost (CPB) is disabled on any core, a P-state limit is applied to all cores. The P-state limit restricts all cores to the highest performance non-boosted P-state. See [2.5.5.1.6 \[Modification of P-state Requests and Visibility\]](#).
- All P-states, both boosted and non-boosted, are specified in [MSRC001\\_00\[6B:64\]](#).
- The number of boosted P-states is specified by [D18F4x15C\[NumBoostStates\]](#).
  - The number of boosted P-states may vary from product to product.
- Two levels of boosted P-states are supported. Compute units can be placed in the first level of boosted P-states if the processor power consumption remains within the TDP limit. The second level of boosted P-states is C-state Boost. See [2.5.9.1.1 \[C-state Boost\]](#).
- All boosted P-states are always higher performance than non-boosted P-states.
- To ensure proper operation, boosted P-states should be hidden from the operating system. BIOS should not

provide ACPI \_PSS entries for boosted P-states. See [2.5.3.1.8.3.2 \[\\_PSS \(Performance Supported States\)\]](#).

- The lowest-performance P-state CPB limits the processor to is the highest-performance non-boosted P-state.

#### **2.5.9.1.1 C-state Boost**

C-state Boost can only be achieved if a subset of compute units are in CC6 and the processor power consumption remains within the TDP limit. See [D18F4x16C](#)[CstateCnt, CstateBoost].

#### **2.5.9.2 TDP Limiting**

TDP limiting is a mechanism for capping the power consumption of the processor through a TDP limit.

#### **2.5.9.3 Bidirectional Application Power Management (BAPM)**

Bidirectional Application Power Management (BAPM) is an algorithm to enable fine grained power transfers between the core and GPU. This algorithm tracks either power or temperature across the processor which enables maximum performance within a defined limit.

## 2.6 Performance Monitoring

The processor includes support for two methods of monitoring processor performance:

- [2.6.1 \[Performance Monitor Counters\]](#).
- [2.6.2 \[Instruction Based Sampling \(IBS\)\]](#).

### 2.6.1 Performance Monitor Counters

The following types of performance counters are supported:

- [2.6.1.1 \[Core Performance Monitor Counters\]](#), consisting of one set located in each core of each compute unit.
- [2.6.1.2 \[L2I Performance Monitor Counters\]](#), consisting of one set located in each compute unit.
- [2.6.1.3 \[NB Performance Monitor Counters\]](#), consisting of one set located in each node.

The accuracy of the performance counters is not ensured. The performance counters are not assured of producing identical measurements each time they are used to measure a particular instruction sequence, and they should not be used to take measurements of very small instruction sequences. The RDPMC instruction is not serializing, and it can be executed out-of-order with respect to other instructions around it. Even when bound by serializing instructions, the system environment at the time the instruction is executed can cause events to be counted before the counter value is loaded into EDX:EAX.

To accurately start counting with the write that enables the counter, disable the counter when changing the event and then enable the counter with a second MSR write.

Writing the performance counters can be useful if there is an intention for software to count a specific number of events, and then trigger an interrupt when that count is reached. An interrupt can be triggered when a performance counter overflows. Software should use the WRMSR instruction to load the count as a two's-complement negative number into the performance counter. This causes the counter to overflow after counting the appropriate number of times.

In addition to the RDMSR instruction, the performance counter registers can be read using a special read performance-monitoring counter instruction, RDPMC. The RDPMC instruction loads the contents of the performance counter register specified by the ECX register, into the EDX register and the EAX register. See [Table 36 \[RDPMC ECX Definition\]](#).

#### 2.6.1.1 Core Performance Monitor Counters

The core performance monitor counters are used by software to count specific non L2 events that occur in a core of the compute unit. Each core of each compute unit provides four 48-bit performance counters. Unless otherwise specified, the events count only the activity of the core, not activity caused by the other core of the compute unit.

[MSRC001\\_00\[03:00\]](#) specify the events to be monitored and how they are monitored. All of the events are specified in [3.23 \[Core Performance Counter Events\]](#). [MSRC001\\_00\[07:04\]](#) are the counters.

All of the events are specified in [3.23 \[Core Performance Counter Events\]](#).

#### 2.6.1.2 L2I Performance Monitor Counters

The L2I performance monitor counters are used by software to count specific L2 events that occur in a core of the compute unit. Unless otherwise specified using the thread masks, the events count the activity of all cores. Each compute unit provides four 48-bit performance counters.

[MSRC001\\_023\[6,4,2,0\]](#) [L2I Performance Event Select ([L2I\\_PERF\\_CTL\[3:0\]](#))] specify the events to be monitored and how they are monitored. [MSRC001\\_023\[7,5,3,1\]](#) [L2I Performance Event Counter ([L2I\\_PERF\\_CTR\[3:0\]](#))] are the counters. Support for [MSRC001\\_023\[7:0\]](#) is indicated by [CPUID Fn8000\\_0001\\_ECX\[PerfCtrExtL2I\]](#).

All of the events are specified in [3.24 \[L2I Performance Counter Events\]](#).

All L2I performance monitor events can be counted on all counters.

All L2I performance events are one event per clock.

### 2.6.1.3 NB Performance Monitor Counters

The NB performance monitor counters are used by software to count specific events that occur in the NB. Each node provides four 48-bit performance counters. Since the northbridge performance counter register are shared by all cores on a node, monitoring of northbridge events should only be performed by one core on a node.

[MSRC001\\_024\[6,4,2,0\]](#) [Northbridge Performance Event Select ([NB\\_PERF\\_CTL\[3:0\]](#))] and [MSRC001\\_024\[7,5,3,1\]](#) [Northbridge Performance Event Counter ([NB\\_PERF\\_CTR\[3:0\]](#))] specify the events to be monitored and how they are monitored. Support for [MSRC001\\_024\[7:0\]](#) is indicated by [CPUID Fn8000\\_0001\\_ECX\[PerfCtrExtNB\]](#).

All of the events are specified in [3.25 \[NB Performance Counter Events\]](#).

All NB performance monitor events can be counted on all counters.

All NB performance events are one event per clock.

NB performance counters do not support APIC interrupt capability.

## 2.6.2 Instruction Based Sampling (IBS)

IBS is a code profiling mechanism that enables the processor to select a random instruction fetch or micro-op after a programmed time interval has expired and record specific performance information about the operation. An interrupt is generated when the operation is complete as specified by [MSRC001\\_103A \[IBS Control\]](#). An interrupt handler can then read the performance information that was logged for the operation.

The IBS mechanism is split into two parts: instruction fetch performance controlled by [MSRC001\\_1030 \[IBS Fetch Control \(IbsFetchCtl\)\]](#); and instruction execution performance controlled by [MSRC001\\_1033 \[IBS Execution Control \(IbsOpCtl\)\]](#). Instruction fetch sampling provides information about instruction TLB and instruction cache behavior for fetched instructions. Instruction execution sampling provides information about micro-op execution behavior. The data collected for instruction fetch performance is independent from the data collected for instruction execution performance. Support for the IBS feature is indicated by the [CPUID Fn8000\\_0001\\_ECX\[IBS\]](#).

Instruction fetch performance is profiled by recording the following performance information for the tagged instruction fetch:

- If the instruction fetch completed or was aborted. See [MSRC001\\_1030](#).
- The number of clock cycles spent on the instruction fetch. See [MSRC001\\_1030](#).
- If the instruction fetch hit or missed the IC, hit/missed in the L1 and L2 TLBs, and page size. See [MSRC001\\_1030](#).

- The linear address, physical address associated with the fetch. See [MSRC001\\_1031](#), [MSRC001\\_1032](#).

Instruction execution performance is profiled by tagging one micro-op associated with an instruction. Instructions that decode to more than one micro-op return different performance data depending upon which micro-op associated with the instruction is tagged. These micro-ops are associated with the RIP of the next instruction to retire. The following performance information is returned for the tagged micro-op:

- Branch and execution status for micro-ops. See [MSRC001\\_1035](#).
- Branch target address for branch micro-ops. See [MSRC001\\_103B](#).
- The logical address associated with the micro-op. See [MSRC001\\_1034](#).
- The linear and physical address associated with a load or store micro-op. See [MSRC001\\_1038](#), [MSRC001\\_1039](#).
- The data cache access status associated with the micro-op: DC hit/miss, DC miss latency, TLB hit/miss, TLB page size. See [MSRC001\\_1037](#).
- The number clocks from when the micro-op was tagged until the micro-op retires. See [MSRC001\\_1035](#).
- The number clocks from when the micro-op completes execution until the micro-op retires. See [MSRC001\\_1035](#).
- Source information for DRAM and MMIO. See [MSRC001\\_1036](#).

## 2.7 Configuration Space

PCI-defined configuration space was originally defined to allow up to 256 bytes of register space for each function of each device; these first 256 bytes are called base configuration space (BCS). It was expanded to support up to 4096 bytes per function; bytes 256 through 4095 are called extended configuration space (ECS). The processor includes configuration space registers located in both BCS and ECS. Processor configuration space is accessed through bus 0, devices 18h to 1Fh, where device 18h corresponds to node 0 and device 1Fh corresponds to node 7. See [2.7.3 \[Processor Configuration Space\]](#).

Configuration space is accessed by the processor through two methods:

- IO-space configuration: IO instructions to addresses CF8h and CFCh.
  - Enabled through [IOCF8\[ConfigEn\]](#), which allows access to BCS.
  - Access to ECS enabled through [MSRC001\\_001F\[EnableCf8ExtCfg\]](#).
  - Use of IO-space configuration can be programmed to generate GP faults through [MSRC001\\_0015\[IoCf-gGpFault\]](#).
  - SMI trapping for these accesses is specified by [MSRC001\\_0054 \[IO Trap Control \(SMI\\_ON\\_IO\\_TRAP\\_CTL\\_STS\)\]](#) and [MSRC001\\_00\[53:50\] \[IO Trap \(SMI\\_ON\\_IO\\_TRAP\\_\[3:0\]\)\]](#).
- MMIO configuration: configuration space is a region of memory space.
  - The base address and size of this range is specified by [MSRC001\\_0058 \[MMIO Configuration Base Address\]](#). The size is controlled by the number of configuration-space bus numbers supported by the system. Accesses to this range are converted configuration space as follows:
    - Address[31:0] = {0h, bus[7:0], device[4:0], function[2:0], offset[11:0]}.

The BIOS may use either configuration space access mechanism during boot. Before booting the OS, BIOS must disable IO access to ECS, enable MMIO configuration and build an ACPI defined MCFG table. BIOS ACPI code must use MMIO to access configuration space.

Per the link specification, BCS accesses utilize link addresses starting at FD\_FE00\_0000h and ECS accesses utilize link addresses starting at FE\_0000\_0000h.

### 2.7.1 MMIO Configuration Coding Requirements

MMIO configuration space accesses must use the uncacheable (UC) memory type.

Instructions used to read MMIO configuration space are required to take the following form:

```
mov eax/ax/al, any_address_mode;
```

Instructions used to write MMIO configuration space are required to take the following form:

```
mov any_address_mode, eax/ax/al;
```

No other source/target registers may be used other than eax/ax/al.

In addition, all such accesses are required not to cross any naturally aligned DW boundary. Access to MMIO configuration space registers that do not meet these requirements result in undefined behavior.

### 2.7.2 MMIO Configuration Ordering

Since MMIO configuration cycles are not serializing in the way that IO configuration cycles are, their ordering rules relative to posted may result in unexpected behavior.

Therefore, processor MMIO configuration space is designed to match the following ordering relationship that exists naturally with IO-space configuration: if a core generates a configuration cycle followed by a posted-write cycle, then the posted write is held in the processor until the configuration cycle completes. As a result, any unexpected behavior that might have resulted if the posted-write cycle were to pass MMIO configuration cycle is avoided.

### 2.7.3 Processor Configuration Space

The processor includes configuration space as described in 3 [Registers]. Accesses to unimplemented registers of implemented functions are ignored: writes dropped; reads return 0. Accesses to unimplemented functions also ignored: writes are dropped; however, reads return all F's. The processor does not log any master abort events for accesses to unimplemented registers or functions.

Accesses to device numbers of devices not implemented in the processor are routed based on the configuration map registers. If such requests are master aborted, then the processor can log the event.

## 2.8 Northbridge (NB)

Each node includes a single northbridge that provides the interface to the local core(s), the interface to system memory, and the interface to system IO devices. The NB includes all power planes except VDD; see 2.5.1 [Processor Power Planes And Voltage Control].

The NB is responsible for routing transactions sourced from cores and link to the appropriate core, cache, DRAM, or link. See 2.4.6 [System Address Map].

### 2.8.1 NB Architecture

Major NB blocks are: System Request Interface (SRI), Memory Controller (MCT), DRAM Controllers (DCTs), and crossbar (XBAR). SRI interfaces with the core(s). MCT maintains cache coherency and interfaces with the DCTs; MCT maintains a queue of incoming requests called MCQ. XBAR is a switch that routes packets between SRI, MCT, and the link.

The MCT operates on physical addresses. Before passing transactions to the DCTs, the MCT converts physical addresses into *normalized* addresses that correspond to the values programmed into D18F2x[5C:40]\_dct[0]

[DRAM CS Base Address]. Normalized addresses include only address bits within the DCTs' range.

## 2.8.2 NB Routing

### 2.8.2.1 Address Space Routing

There are four main types of address space routed by the NB:

1. Memory space targeting system DRAM
2. Memory space targeting IO (MMIO)
3. IO space
4. Configuration space.

#### 2.8.2.1.1 DRAM and MMIO Memory Space

Memory space transactions provide the NB with the physical address, cacheability type, access type, and DRAM/MMIO destination type as specified in section 2.4.6.1.2 [Determining The Access Destination for Core Accesses].

Memory-space transactions are handled by the NB as follows:

- IO-device accesses are compared against:
  - If the access matches [D18F1x\[2CC:2A0,1CC:180,BC:80\]](#) [MMIO Base/Limit], then the transaction is routed to the root complex;
  - Else, if the access matches [D18F1x\[17C:140,7C:40\]](#) [DRAM Base/Limit], then the access is routed to the DCT;
  - Else, the access is routed to the UMI.
- For core accesses the routing is determined based on the DRAM/MMIO destination:
  - If the destination is DRAM:
    - Else, if the access matches [D18F1x\[17C:140,7C:40\]](#) [DRAM Base/Limit], then the transaction is routed to the DCT;
    - Else, the access is routed to the UMI.
  - If the destination is MMIO:
    - If the access matches the VGA-compatible MMIO address space and [D18F1xF4\[VE\]=1](#) then [D18F1xF4](#) describes how the access is routed and controlled;
    - Else, If the access matches [D18F1x\[2CC:2A0,1CC:180,BC:80\]](#) [MMIO Base/Limit], then the transaction is routed to the root complex;
    - Else, the access is routed to the UMI.

#### 2.8.2.1.2 IO Space

IO-space transactions from IO links or cores are routed as follows:

- If the access matches [D18F1x\[DC:C0\]](#) [IO-Space Base/Limit], then the transaction is routed to the root complex;
- Else, If the access matches the VGA-compatible IO address space and [D18F1xF4\[VE\]=1](#) then [D18F1xF4](#) describes how the access is routed and controlled.
- Else, the access is routed to the UMI.

#### 2.8.2.1.3 Configuration Space

Configuration-space transactions from IO links are master aborted. Configuration-space transactions from cores are routed as follows:

- If the access matches [D18F1x\[1DC:1D0,EC:E0\]](#) [Configuration Map], then the transaction is routed to the specified link;
- Else, the access is routed to link that contains compatibility (subtractive) address space.

### 2.8.2.1.3.1 Recommended Buffer Count Settings Overview

When changing from the recommended settings, see the register programming requirements in the definition of each register. Some chipsets may further optimize these settings for their platform. If values other than the recommended settings are used, see the register requirements in the definition of each register. [Table 11](#) defines commonly used terms for the following tables.

**Table 11: ONION Link Definitions**

| Term       | Definition  |
|------------|-------------|
| LinkGanged | Ganged = 0. |

### 2.8.3 Memory Scrubbers

The processor includes memory scrubbers specified in [MSRC001\\_10A0](#), [D18F3x58](#), [D18F3x5C](#), and [D18F3x60](#). The scrubbers ensure that all cachelines in memory within or connected to the processor are periodically read and, if correctable errors are discovered, they are corrected.

For recommendations on scrub rates, see [2.14.1.8 \[Scrub Rate Considerations\]](#).

The scrub rate is specified as the time between successive scrub events. A scrub event occurs when a line of memory is checked for errors; the amount of memory that is checked varies based on the memory block (see field descriptions).

The time required to fully scrub the memory of a node is determined as:

- $\text{Time} = ((\text{memory size in bytes})/64) * (\text{Scrub Rate})$ .
- E.g. If a node contains 1GB of system memory and  $\text{DramScrub}=5.24 \text{ ms}$ , then all of the system memory of the node is scrubbed about once every 23 hours.

## 2.9 DRAM Controllers (DCTs)

The processor includes one DRAM controller (DCT). Each DCT controls one 64-bit DDR3 DRAM channel.

A DRAM channel consists of the group of DRAM interface pins connecting to one series of DIMMs.

BIOS reads [D18F5x84\[DctEn\]](#) to determine the DCT to DDR channel mapping as follows:

- DCT0 controls channel A.

The DCTs operate on normalized addresses corresponding to the values programmed into [D18F2x\[5C:40\]\\_dct\[0\]](#). Normalized addresses only include address bits within a DCT's range. The physical to normalized address translation varies based on various Northbridge settings. See [2.9.10 \[Memory Hoisting\]](#) and [2.9.11 \[DRAM CC6/PC6 Storage\]](#).

The following restrictions limit the DIMM types and configurations supported by the DCT:

- All DIMMs connected to a node are required to operate at the same MEMCLK frequency, regardless of the channel. All DCTs of a node must be programmed to the same frequency.
- Mixing of DIMM types within a system is not supported.
- RDIMM, LRDIMM, and stacked DRAM type DIMMs are not supported.
- Mixing of ECC and non-ECC DIMMs within a system is not supported

### 2.9.1 Common DCT Definitions

**Table 12: DCT Definitions**

| Term                             | Definition                                                                                                                                                                                                                                                                                       |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>AutoSelfRefresh</b>           | SPDByte[31][2] of the DIMM being configured.                                                                                                                                                                                                                                                     |
| <b>DataMaskMbType</b>            | Motherboard type for processor Data Mask pins.<br><div> <div>Bits</div> <div>Description</div> </div> <div> <div>00b</div> <div>No connect</div> </div> <div> <div>01b</div> <div>Pins are routed per DM rules</div> </div> <div> <div>10b</div> <div>Pins are routed per DQS rules</div> </div> |
| <b>DdrRate</b>                   | The DDR data rate (MT/s) as specified by <a href="#">D18F2x94_dct[0][MemClkFreq]</a> and <a href="#">D18F2x2E0_dct[0][M1MemClkFreq]</a> .                                                                                                                                                        |
| <b>DeviceWidth</b>               | SPDByte[7][2:0] of the DIMM being configured.                                                                                                                                                                                                                                                    |
| <b>DIMM</b>                      | The DIMM being configured                                                                                                                                                                                                                                                                        |
| <b>DIMM0</b>                     | DIMM slots 0-n. The DIMMs on each channel are numbered from 0 to n where DIMM0 is the DIMM closest to the processor on that channel and DIMMn is the DIMM farthest from the processor on that channel.                                                                                           |
| <b>DIMM1</b>                     |                                                                                                                                                                                                                                                                                                  |
| <b>DimmsPopulated</b>            | The number of DIMMs populated per channel plus rows of <a href="#">Solder-down DRAM</a> devices.                                                                                                                                                                                                 |
| <b>DR</b>                        | Dual Rank                                                                                                                                                                                                                                                                                        |
| <b>DramCapacity</b>              | SPDByte[4][3:0] of the DIMM being configured.                                                                                                                                                                                                                                                    |
| <b>ExtendedTemperature-Range</b> | SPDByte[31][0] of the DIMM being configured.                                                                                                                                                                                                                                                     |
| <b>MRS</b>                       | JEDEC defined DRAM Mode Register Set.                                                                                                                                                                                                                                                            |
| <b>NP</b>                        | No DIMM populated                                                                                                                                                                                                                                                                                |

**Table 12: DCT Definitions**

| Term                    | Definition                                                                                                                                       |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NumDimmSlots</b>     | The number of motherboard DIMM slots per channel plus rows of <b>Solder-down DRAM</b> devices                                                    |
| <b>NumRanks</b>         | SPDByte[7][5:3] of the DIMM being configured, or the number of ranks soldered down.                                                              |
| <b>Rank</b>             | The rank being configured                                                                                                                        |
| <b>RankMap</b>          | SPDByte[63][0] of the DIMM being configured.                                                                                                     |
| <b>RowAddrBits</b>      | SPDByte[5][5:3] of the DIMM being configured.                                                                                                    |
| <b>Solder-down DRAM</b> | DRAM devices soldered directly to the motherboard.                                                                                               |
| <b>SODIMM</b>           | DCT is configured for SODIMM if (D18F2x90_dct[0][UnbuffDimm]==1) and SODIMMs are populated.                                                      |
| <b>SPD</b>              | Serial Presence Detect. In the case of DRAMs soldered on the platform, this refers to a virtual representation of the DRAM vendors' data sheets. |
| <b>SR</b>               | Single Rank                                                                                                                                      |
| <b>UDIMM</b>            | DCT is configured for UDIMM if (D18F2x90_dct[0][UnbuffDimm]==1) and UDIMMs are populated.                                                        |
| <b>VDDIO</b>            | DDR VDDIO in V.                                                                                                                                  |

### 2.9.2 DCT Frequency Support

The tables below list the maximum DIMM speeds supported by the processor for different configurations. The motherboard should comply with the relevant AMD socket motherboard design guideline (MBDG) to achieve the rated speeds. In cases where MBDG design options exist, lower-quality options may compromise the maximum achievable speed; motherboard designers should assess the tradeoffs.

**Table 13: DDR3 UDIMM Maximum Frequency Support with 6-layer Motherboard Design FT3 package**

| Num-DimmSlots                                                                                | Dimms Populated | DRAM |    | Frequency <sup>1</sup> (MT/s) |       |       |
|----------------------------------------------------------------------------------------------|-----------------|------|----|-------------------------------|-------|-------|
|                                                                                              |                 | SR   | DR | 1.5V                          | 1.35V | 1.25V |
| 1                                                                                            | 1               | 1    | -  | 1600                          | -     | -     |
|                                                                                              |                 | -    | 1  | 1600                          | -     | -     |
| 2                                                                                            | 1               | 1    | -  | 1600                          | -     | -     |
|                                                                                              |                 | -    | 1  | 1600                          | -     | -     |
|                                                                                              | 2               | 2    | -  | 1600                          | -     | -     |
|                                                                                              |                 | 1    | 1  | 1333                          | -     | -     |
|                                                                                              |                 | -    | 2  | 1333                          | -     | -     |
| 1. Population restrictions (including the order for partially populated channels) may apply. |                 |      |    |                               |       |       |

The tables below list the DIMM populations as supported by the processor. DIMMs must be populated from farthest slot to closest slot to the processor on a per channel basis when a daisy chain topology is used.

Table 22: DDR3 Population Support

| NumDimmSlots | DIMM0 | DIMM1 |
|--------------|-------|-------|
| 1            | SR/DR | N/A   |
| 2            | NP    | SR/DR |
|              | SR/DR | SR/DR |

### 2.9.3 DCT Configuration Registers

There are multiple types of DCT configuration registers:

- Registers for which there is one instance. E.g. [D18F2xA4](#) or [D18F2x78\\_dct\[0\]](#).
- Registers for which there is one instance per NbPstate use [D18F1x10C\[NbPsSel\]](#) for software accesses.
  - [D18F2x210\\_dct\[0\]\\_nbp\[3:0\]](#) refers to all instances of the D18F2x210 register.
  - [D18F2x210\\_dct\[0\]\\_nbp\[1\]](#) refers to the register for Nb P-state 1 of any or all DCTs.
- Registers for which there is one instance per memory P-state use [D18F1x10C\[MemPsSel\]](#) for software accesses. The syntax for this register type is described by example as follows:
  - [D18F2x2E8\\_dct\[0\]\\_mp\[1:0\]](#) refers to all instances of the D18F2x2E8 register.
  - [D18F2x2E8\\_dct\[0\]\\_mp\[1\]](#) refers to the register for memory P-state 1 of either or both DCTs.

## 2.9.4 DDR Pad to Processor Pin Mapping

The relationship of pad drivers to processor pins varies by package as shown in the following table. The pad names in the tables below may be prefixed with “BP\_” to obtain the correct bump name.

**Table 23: Package pin mapping**

| Pad                                                                                                                                                                                                                                                  | Pin <sup>1</sup> |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
|                                                                                                                                                                                                                                                      | FT3              |
| MEMCLK0_H[0]                                                                                                                                                                                                                                         | MA_CLK_H[0]      |
| MEMCLK0_H[1]                                                                                                                                                                                                                                         | MA_CLK_H[1]      |
| MEMCLK0_H[2]                                                                                                                                                                                                                                         | MA_CLK_H[2]      |
| MEMCLK0_H[3]                                                                                                                                                                                                                                         | MA_CLK_H[3]      |
| MEMCLK0_H[4]                                                                                                                                                                                                                                         | NC               |
| MEMCLK0_H[5]                                                                                                                                                                                                                                         | NC               |
| MEMCS0_L[0]                                                                                                                                                                                                                                          | MA0_CS_L[0]      |
| MEMCS0_L[1]                                                                                                                                                                                                                                          | MA0_CS_L[1]      |
| MEMCS0_L[2]                                                                                                                                                                                                                                          | MA1_CS_L[0]      |

| MEMODT0[3]                                                                                                                                                                                                                                           | MA1_ODT[1]       |
| MEMCKE0[0]                                                                                                                                                                                                                                           | MA_CKE[0]        |
| MEMCKE0[1]                                                                                                                                                                                                                                           | MA_CKE[1]        |
| MEMCKE0[2]                                                                                                                                                                                                                                           | MA_CKE[2]        |
| MEMCKE0[3]                                                                                                                                                                                                                                           | MA_CKE[3]        |
| 1. For differential pins, only positive polarity pins are shown; negative polarity pins have corresponding mapping and are controlled by the same CSR field. NC = Not connected. BIOS should tri-state or disable the pad for maximum power savings. |                  |

### 2.9.4.1 DDR Chip to Pad Mapping

The relationship of chip to pad drivers is shown in the following table. BIOS should disable or power down unused chips for maximum power savings.

**Table 24: Pad (from chiplet) pin mapping**

| Chip                                                                                                                                                                                                                                                                                                                                                                                                            | Group | Pad <sup>1</sup>         |

| Data <sup>2</sup>                                                                                                                                                                                                                                                                                                                                                                                               | 0     | MEMDATA[5,4,1,0]         |
|                                                                                                                                                                                                                                                                                                                                                                                                                 | 1     | MEMDQS_H[0], MEMDQSDM[0] |
|                                                                                                                                                                                                                                                                                                                                                                                                                 | 2     | MEMDATA[7,6,3,2]         |
| <ol style="list-style-type: none"> <li>For differential pads, only positive polarity pads are shown; negative polarity pads have corresponding mapping and are controlled by the same chip.<br/>Only channel A map is shown. For multi-channel products the other channels are similar.</li> <li>Only Data chip 0 is shown. Remaining data chips are repeated with sequential DQ/DQS/DM pin numbers.</li> </ol> |       |                          |

### 2.9.5 DRAM Controller Direct Response Mode

The DCT supports direct response mode for responding to a cache line fill request before the DCT is initialized. In direct response mode, the target DCT responds to a cache line fill request by returning 64 bytes of all ones without issuing a read transaction on the DRAM bus. The BIOS uses this feature, a.k.a dummy response mode, or, graceful abort, to allocate cache lines for temporary data storage. The controller exits direct response mode when [D18F2x7C\\_dct\[0\]\[EnDramInit\]](#) or [D18F2x90\\_dct\[0\]\[InitDram\]\[ExitSelfRef\]](#) is set to 1. See [2.3.3 \[Using L2 Cache as General Storage During Boot\]](#).

### 2.9.6 DRAM Data Burst Mapping

DRAM requests are mapped to data bursts on the DDR bus in the following order:

- When [D18F2x110\[DctDatIntLv\]](#) = 0, a 64 B request is mapped to each of the eight sequential data beats as QW0, QW1...QW7.
- When [D18F2x110\[DctDatIntLv\]](#) = 1, the order of cache data to QW on the bus is the same except that even

and odd bits are interleaved on the DRAM bus as follows:

- For every 8 bytes in the cache line, even bits map to QW0, QW2, QW4, and QW6 on the DRAM bus.
- For every 8 bytes in the cache line, odd bits map to QW1, QW3, QW5, and QW7 on the DRAM bus.

## 2.9.7 DCT/DRAM Initialization and Resume

DRAM initialization involves several steps in order to configure the DRAM controllers and the DRAM, and to tune the DRAM channel for optimal performance.

DRAM resume requires several steps to configure the DCTs to properly resume from the S3 state.

The following sequence describes the steps needed after a reset for initialization or resume:

1. Configure the DDR supply voltage regulator. See 2.9.7.1.
2. Force NB P-state to NBP0.
3. Force register accesses to M0. See 2.9.7.3 for further requirements used in steps below.
4. DDR phy initialization. See 2.9.7.4.
5. DRAM device and controller initialization.
  - If BIOS is booting from an unpowered state (ACPI S4, S5 or G3), then it performs the following:
    - a. Program SPD configuration. See 2.9.7.5.
    - b. Program Non-SPD configuration. See 2.9.7.6.
    - c. Program DCT training specific configuration. See 2.9.7.7.
    - d. Program the remaining DCT registers not covered by an explicit sequence dependency.
    - e. DRAM device initialization. See 2.9.7.8.
  - If BIOS is resuming the platform from S3 state, then it performs the following:
    - a. Restore all DCT and phy registers that were programmed during the first boot from non-volatile storage. See 2.9.7.5 and 2.9.7.6 for a review of registers.
    - b. Program D18F2x90\_dct[0][ExitSelfRef] = 1. Dct sends MR0.
    - c. Restore the trained delayed values (found during the initial boot in step 6 below) from nonvolatile storage.
    - d. Continue at step 8.
6. DRAM data training.
  - A. Write levelization training. See 2.9.7.9.1.
  - B. DQS receiver enable training. See 2.9.7.9.2 and 2.9.7.9.3.
  - C. DQS position training. See 2.9.7.9.4.
7. NB P-state specific training. For each NB P-state to D18F5x170[NbPstateMaxVal]:
  - A. Force the NB P-state. See 2.9.7.2.
  - B. MaxRdLatency training. See 2.9.7.9.5.1. Programs NBPx version.
8. Release NB P-state force.
9. Program DRAM phy for power savings. See 2.9.7.10.
10. Program DCT for normal operation. See 2.9.7.7.

The DRAM subsystem is ready for use.

### 2.9.7.1 Low Voltage DDR3

The processor supports JEDEC defined DDR3L and DDR3U devices which operate at voltages lower than 1.5V.

Platforms supporting low voltage devices should power up VDDIO at 1.35V. BIOS should not indefinitely operate DIMMs at voltages higher than supported as indicated by SPD Byte 6: Module Nominal Voltage, VDD.

BIOS should consult vendor data sheets for the supply voltage regulator programming requirements. On supported platforms, BIOS must take steps to configure the supply voltage regulators as follows:

1. Read the SPD of all DIMMs within the programmable VDDIO domain and check all of the defined bits within the SPD byte to determine the common operating voltages. (SPD Byte 6, Bits [2:0] indicate support for 1.25V, 1.35V, 1.5V operation. Refer to the JEDEC specification).
2. Configure VDDIO to match the lowest common supported voltage based on the SPD values.
  - If the DIMMs do not specify a common operating voltage then BIOS must take platform vendor defined action to notify the end user of the mismatch and to protect DIMMs from damage. AMD suggests the following possible actions: Configure VDDIO for 1.35V; configure all DIMMs to run at the lowest frequency supported by the DIMMs and the processor; configure 1.5V-only DIMMs with F2x[1, 0][5C:40][TestFail] bit set prior to sending MRS commands and exclude those DIMMs from the system address map; notify the user of the mismatch. The vendor retains all responsibility for operating mismatched DIMMs.
3. Additional derating of the DDR speed may be necessary for reliable operation at lower voltage. See [2.9.2 \[DCT Frequency Support\]](#).

### 2.9.7.2 NB P-state Specific Configuration

A subset of DCT configuration and training must be repeated for each enabled NB P-state. To accomplish this, BIOS forces the processor to the desired NB P-state and releases the force once DRAM initialization and training is complete. See [2.5.4.1 \[NB P-states\]](#) and [2.5.4.1.2.2 \[NB P-state Transitions\]](#).

### 2.9.7.3 Memory P-state Specific Configuration

A subset of DCT configuration and training must be repeated for each enabled memory P-state. See also [2.5.7.1 \[Memory P-states\]](#).

To accomplish this, BIOS forces the processor to the NBP0 state and uses the M0 context to train for values that are used by all memory P-states. For example, BIOS uses [D18F2x94\\_dct\[0\]\[MemClkFreq\]](#) to specify the dram frequency during each pass of training. BIOS saves the trained configuration values at each step and uses them appropriately as outlined below:

1. Force NB P-state to NBP0. See [2.9.7.2](#).
2. Program [D18F1x10C\[MemPsSel\]](#)=0. Force memory P-state DCT CSR access context to M0. See [2.9.3](#).
3. Program [D18F2x9C\\_x0D04\\_E008\\_dct\[0\]\[PStateToAccess\]](#)=0. Force memory P-state PHY CSR access context to M0.
4. Using the M0 context, BIOS optimally configures the controller and trains at DDR667 according to [2.9.7](#) steps 4 thru 7. Tcl, Trcd, Trp configured per best practices, etc.
  - A. BIOS saves the trained values for use in M1 and for subsequent higher frequencies.
  - B. BIOS saves the controller configuration for use in M1.
  - C. BIOS optimally writes all the values to registers in step 6. It may optionally write the values as each is computed or trained. If this is done then BIOS must ensure that [D18F1x10C\[MemPsSel\]](#) and [D18F2x9C\\_x0D04\\_E008\\_dct\[0\]\[PStateToAccess\]](#) are configured correctly before and after each register access.
5. BIOS increases the frequency and repeats step 4 until the target frequency is trained. The target frequency is always associated with M0.
6. BIOS programs the M1 controller context with the DDR667 configuration and trained results. This step may optionally be performed after the first pass of step 4 above. This must be done before the next subsequent NB P-state change.
  - a. Program [D18F1x10C\[MemPsSel\]](#)=1.
  - b. Program [D18F2x9C\\_x0D04\\_E008\\_dct\[0\]\[PStateToAccess\]](#) = 1.
  - c. Program [D18F2x2E0\\_dct\[0\]\[M1MemClkFreq\]](#) and [D18F2x9C\\_x0D0F\\_E000\\_dct\[0\]\\_mp\[1\]\[Rate, FreqValid\]](#) = {04h, 1}. 667 MT/s

- d. Program DCT configuration and trained delay values saved earlier.  
Three groups of registers must be written in the same order as the initialization sequence so h/w correctly computes fence bits:
  - Fence values: `D18F2x9C_x0000_000C_dct[0]`, `D18F2x9C_x0D0F_0[F,8:0]31_dct[0]`, `D18F2x9C_x0D0F_E019_dct[0]`.
  - Address/Command timing delays: `D18F2x9C_x0000_0004_dct[0]_mp[1:0]`.
  - All other Data/Dqs delays: See step 6 in section 2.9.7.
- e. Program `D18F2x9C_x0D04_E008_dct[0][PStateToAccess]` = 0.
- f. Program `D18F1x10C[MemPsSel]` = 0.

#### 2.9.7.4 DDR Phy Initialization

The BIOS initializes the phy and the internal interface from the DCT to the phy, including the PLLs and the fence value, after each reset and for each time a MEMCLK frequency change is made.

BIOS obtains size, loading, and frequency information about the DIMMs and channels using SPDs prior to phy initialization. BIOS then performs the following actions:

1. Program `D18F2x9C_x0D0F_E013_dct[0]` = 0118h.
2. For each byte lane and each memory P-state: Program `D18F2x9C_x0D0F_0[F,8:0]13_dct[0]_mp[1:0][RxSsbMntClkEn]` = 0.
3. Program `D18F2xA8_dct[0][MemPhyPlIPdMode]` = 00b.
4. Force the phy to M0 with the following sequence.
  - A. Program `D18F2x9C_x0D0F_E006_dct[0][PlILockTime]` = 190h. Restore the default PLL lock time.
  - B. Program `D18F2x9C_x0000_000B_dct[0]` = 80800000h. ESR
  - C. Program `D18F2x9C_x0000_000D18F2x9C_x0000_000B_dct[0]` = 40000000h. PhyPSR. Note: BIOS performs the sequence only on DCTs with an enabled interface (`D18F2x94_dct[0][DisDramInterface]==0`).
  - D. For each DCT: Program `D18F2x9C_x0000_000B_dct[0]` = 80000000h. XSR
5. Phy Voltage Level Programming. See 2.9.7.4.1.
6. DRAM channel frequency change. See 2.9.7.4.2.
7. Phy fence programming. See 2.9.7.4.3.
8. Phy compensation initialization. See 2.9.7.4.4.

##### 2.9.7.4.1 Phy Voltage Level Programming

BIOS programs the following according to the desired phy VDDIO voltage level:

- Program `D18F2x9C_x0D0F_0[F,8:0]1F_dct[0]_mp[1:0][RxVioLvl]`.
  - Program `D18F2x9C_x0D0F_[C,8,2][2:0]1F_dct[0][RxVioLvl]`.
  - Program `D18F2x9C_x0D0F_4009_dct[0][CmpVioLvl,ComparatorAdjust]`.
  - Program `D18F2x9C_x0D0F_4006_dct[0][VrefSel]` = 0.
  - Program `D18F2x9C_x0D0F_4007_dct[0]` per platform requirements.
- See 2.9.7.1 [Low Voltage DDR3].

##### 2.9.7.4.2 DRAM Channel Frequency Change

The following sequence is used to change the DRAM frequency under all boot conditions, including restoring the DCT state when resuming from the S3 state. BIOS performs the sequence only on DCTs with an enabled interface (`D18F2x94_dct[0][DisDramInterface]==0`):

For each DCT:

1. Program `D18F2x9C_x0D0F_E006_dct[0][PlILockTime]` = 190h. Restore the default PLL lock time.

2. Program `D18F2x94_dct[0][MemClkFreqVal]` = 0.
3. Program `D18F2x94_dct[0][MemClkFreq]` to the desired DRAM frequency.
4. Program the following parameters which must be configured prior to setting `MemClkFreqVal`:
  - `D18F2x94_dct[0][ProcOdtDis]`
  - `D18F2x9C_x0000_0004_dct[0]_mp[1:0]`
  - `D18F2x9C_x0D0F_0[F,8:0]13_dct[0]_mp[1:0][ProcOdtAdv]`
  - `D18F2x210_dct[0]_nbp[3:0][RdPtrInit, DataTxFifoWrDly]` of the current NB P-state for the target MEMCLK frequency. See also 2.9.7.2.
  - IF (target `DdrRate` >= 1600) `D18F2x9C_x0D0F_0[F,8:0]38_dct[0][ReducedLoop]` = 10b ENDIF.

For each DCT:

5. Program `D18F2x94_dct[0][MemClkFreqVal]` = 1. Wait for `D18F2x94_dct[0][FreqChgInProg]` = 0.

For each DCT:

6. Program `D18F2x9C_x0D0F_E006_dct[0][PllLockTime]` according to Table 25.

BIOS must observe the following requirements:

- BIOS must not change the PLL frequency after DRAM has exited from self-refresh.
- BIOS must not change the PLL frequency after the DRAM training for DDR3 DIMMs is complete.

**Table 25: DDR PLL Lock Time**

| <code>D18F2x94_dct[0][MemPhyPllPdMode]</code> | <code>PllLockTime</code> |
|-----------------------------------------------|--------------------------|
| 00b                                           | 0Fh                      |
| 10b                                           | 190h                     |

#### 2.9.7.4.2.1 Requirements for DRAM Frequency Change During Training

During DRAM training, BIOS may be required to change the DRAM(MEMCLK) frequency. The steps below describe what is required to prepare the processor and memory subsystem for the new MEMCLK frequency. It is assumed that the memory subsystem has previously been initialized at the current MEMCLK frequency, and this procedure describes only the steps that must be repeated at the new MEMCLK frequency. See 2.9.7.9.1 [Write Levelization Training] and 2.9.7.9.2 [DQS Receiver Enable Training].

1. Force the NB P-state. See 2.9.7.2.
2. Enter self-refresh:
  - A. Program `D18F2x90_dct[0][DisDllShutdownSR]` = 1.
  - B. Program `D18F2x90_dct[0][EnterSelfRef]` = 1.
  - C. Wait for `D18F2x90_dct[0][EnterSelfRef]` = 0.
3. DRAM channel frequency change. See 2.9.7.4.2.
4. Change NCLK frequency to meet NCLK-MEMCLK ratio requirements. See 2.5.3.1.5.
5. Phy fence programming. See 2.9.7.4.3.
6. Phy compensation initialization. See 2.9.7.4.4.
7. Program SPD configuration. See 2.9.7.5. Re-program frequency dependent parameters according to the new frequency (Twr, Tcwl, Tcl, etc.).
8. Program Non-SPD configuration. See 2.9.7.6. Re-program frequency dependent parameters according to the new frequency (ODT, addr/cmd timings, etc.).
9. Exit self-refresh:
  - A. Program `D18F2x90_dct[0][ExitSelfRef]` = 1.
  - B. Wait for `D18F2x90_dct[0][ExitSelfRef]` = 0.
  - C. Program `D18F2x90_dct[0][DisDllShutdownSR]` = 0.
10. Re-program devices with frequency dependent mode register field values. See 2.9.7.8. (Twr, Tcwl, Tcl,

etc.).

### 2.9.7.4.3 Phy Fence Programming

The DDR phy fence logic is used to adjust the phase relationship between the data fifo and the data going to the pad. After any MEMCLK frequency change and before any memory training, BIOS must perform phy fence training for each channel using the following steps:

1. Program `D18F2x9C_x0D0F_0[F,8:0]31_dct[0]` = 0000\_0000h.
2. Program `D18F2x9C_x0D0F_E019_dct[0]` = 0000\_0000h.
3. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][FenceTrSel]` = 10b.
4. Program `D18F2x9C_x0000_00[52:50]_dct[0]` = 1313\_1313h.
5. Perform phy fence training. See 2.9.7.4.3.1 [Phy Fence Training].
6. Write the calculated fence value to `D18F2x9C_x0000_000C_dct[0][FenceThresholdTxDll]`.
7. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][FenceTrSel]` = 01b.
8. Program `D18F2x9C_x0000_00[52:50]_dct[0]` = 1313\_1313h.
9. Perform phy fence training. See 2.9.7.4.3.1 [Phy Fence Training].
10. Write the calculated fence value to `D18F2x9C_x0000_000C_dct[0][FenceThresholdRxDll]`.
11. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][FenceTrSel]` = 11b.
12. Program `D18F2x9C_x0000_00[52:50]_dct[0]` = 1313\_1313h.
13. Perform phy fence training. See 2.9.7.4.3.1 [Phy Fence Training].
14. Write the calculated fence value to `D18F2x9C_x0000_000C_dct[0][FenceThresholdTxPad]`.
15. Program Fence2 threshold for data as follows:
  - A. IF `(D18F2x9C_x0000_000C_dct[0][FenceThresholdTxPad] < 16)` THEN  
     `Fence2_TxPad[4:0] = {1b, D18F2x9C_x0000_000C_dct[0][19:16]}`  
 ELSE  
     `Fence2_TxPad[4:0] = 00000b`  
 ENDIF.
  - B. IF `(D18F2x9C_x0000_000C_dct[0][FenceThresholdRxDll] < 16)` THEN  
     `Fence2_RxDll[4:0] = {1b, D18F2x9C_x0000_000C_dct[0][24:21]}`  
 ELSE  
     `Fence2_RxDll[4:0] = 00000b`  
 ENDIF.
  - C. IF `(D18F2x9C_x0000_000C_dct[0][FenceThresholdTxDll] < 16)` THEN  
     `Fence2_TxDll[4:0] = {1b, D18F2x9C_x0000_000C_dct[0][29:26]}`  
 ELSE  
     `Fence2_TxDll[4:0] = 00000b`  
 ENDIF.
  - D. Program `D18F2x9C_x0D0F_0[F,8:0]31_dct[0]` = {000000b, `Fence2_TxDll[4:0]`,  
     `Fence2_TxPad[4:0]}`.
  - E. Program `D18F2x9C_x0D0F_E019_dct[0]` = {0b, `Fence2_RxDll[4:0]`, 00000b, `Fence2_TxPad[4:0]}`.
16. Reprogram `D18F2x9C_x0000_0004_dct[0]_mp[1:0]`. This forces the phy to recompute the fence.

When resuming from S3, BIOS reprograms `D18F2x9C_x0000_000C_dct[0][FenceThresholdTxDll]`, `FenceThresholdRxDll`, `FenceThresholdTxPad`, and `D18F2x9C_x0D0F_E019_dct[0]` from values stored in non-volatile storage instead of training. BIOS reprograms `D18F2x9C_x0D0F_0[F,8:0]31_dct[0]` and `D18F2x9C_x0D0F_E019_dct[0]` as indicated in the steps above.

BIOS may use `D18F2x9C_x0000_000C_dct[0]` and `D18F2x9C_x0D0F_E01A_dct[0]` for local storage of fence values during the intermediate time between training and writing the values into non-volatile storage in preparation for S3.

### 2.9.7.4.3.1 Phy Fence Training

1. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][PhyFenceTrEn]=1`. The PRE tracks phase sign using coarse delay bits. For all lanes, the Tx insertion delay, the phase between PCLK and the DLL output clock, is greater than 0 and less than 1 UI; therefore a seed value is not necessary.
2. Wait 2000 MEMCLKs.
3. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][PhyFenceTrEn]=0`.
4. Read the phase recovery engine registers `D18F2x9C_x0000_00[52:50]_dct[0]`.
5. Calculate the average of the fine delay values of all byte lanes. If FenceTrSel != 00b subtract 8. If the result is negative then the fence value is zero.

### 2.9.7.4.4 Phy Compensation Initialization

Each DDR IO driver has a programmable slew rate controlled by the pre-driver calibration code. The recommended slew rate is a function of the DC drive strength. BIOS initializes the recommended nominal slew rate values as follows:

1. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][DisAutoComp] = 1`.
2. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][DisablePredriverCal]=1`.
3. Program TxPreP/TxPreN for Data and DQS according to [Table 26](#), [Table 27](#), or [Table 28](#).
  - A. Program `D18F2x9C_x0D0F_0[F,8:0]0[A,6]_dct[0]={0000b, TxPreP, TxPreN}`.
  - B. Program `D18F2x9C_x0D0F_0[F,8:0]02_dct[0]={1000b, TxPreP, TxPreN}`.
4. Program TxPreP/TxPreN for Cmd/Addr according to [Table 29](#), [Table 30](#), or [Table 31](#).
  - A. Program `D18F2x9C_x0D0F_[C,8][1:0][12,0E,0A,06]_dct[0]={0000b, TxPreP, TxPreN}`.
  - B. Program `D18F2x9C_x0D0F_[C,8][1:0]02_dct[0]={1000b, TxPreP, TxPreN}`.
5. Program TxPreP/TxPreN for Clock according to [Table 32](#), [Table 33](#), or [Table 34](#).
  - A. Program `D18F2x9C_x0D0F_2[2:0]02_dct[0]={1000b, TxPreP, TxPreN}`.
6. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][DisAutoComp] = 0`.

### 2.9.7.5 SPD ROM-Based Configuration

The Serial Presence Detect (SPD) ROM is a non-volatile memory device on the DIMM encoded by the DIMM manufacturer. The description of the SPD is usually provided on a data sheet for the DIMM itself along with data describing the memory devices used. The data describes configuration and speed characteristics of the DIMM and the SDRAM components mounted on the DIMM. The associated data sheet also contains the DIMM byte values that are encoded in the SPD on the DIMM.

BIOS reads the values encoded in the SPD ROM through a system-specific interface. BIOS acquires DIMM configuration information, such as the amount of memory on each DIMM, from the SPD ROM on each DIMM and uses this information to program the DRAM controller registers.

For solder-down DRAM, in the absence of an SPD ROM, BIOS provides the information necessary for DRAM configuration. For convenience, this document may refer to solder-down DRAM as a DIMM, and to DRAM data sheet or JEDEC DRAM specifications as SPD ROM based, unless otherwise noted.

The SPD ROM provides values for several DRAM timing parameters that are required by the DCT. In general, BIOS should use the optimal value specified by the SPD ROM. These parameters are:

- [D18F2x8C\\_dct\[0\]\[Tref\]](#): See SPD Byte 31: SDRAM Thermal and Refresh Options
- [D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Tras\]](#): Active to precharge time
- [D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Trp\]](#): Precharge time
- [D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Trcd\]](#): RAS to CAS delay
- [D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Tcl\]](#): CAS latency
- [D18F2x204\\_dct\[0\]\\_mp\[1:0\]\[Trtp\]](#): Internal read to precharge command delay time

- [D18F2x204\\_dct\[0\]\\_mp\[1:0\]\[FourActWindow\]](#): Four activate window delay time
- [D18F2x204\\_dct\[0\]\\_mp\[1:0\]\[Trrd\]](#): Row active to row active delay
- [D18F2x204\\_dct\[0\]\\_mp\[1:0\]\[Trc\]](#): Active to active/refresh time
- [D18F2x208\\_dct\[0\]\[Trfc3, Trfc2, Trfc1, Trfc0\]](#): Refresh recovery delay time
- [D18F2x20C\\_dct\[0\]\\_mp\[1:0\]\[Twtr\]](#): Internal write to read command delay time
- [D18F2x22C\\_dct\[0\]\\_mp\[1:0\]\[Twr\]](#): Write recovery time

Optimal cycle time is specified for each DIMM and is used to limit or determine bus frequency. See [2.9.7.8 \[DRAM Device and Controller Initialization\]](#).

The DRAM data sheet or the JEDEC DRAM specification provides values for some DRAM timing parameters that are required by the DCT, regardless of whether the DRAMs are solder-down. Most of these parameters have a fixed time component as part of their specification. If memory P-states are supported (See [2.5.7.1 \[Memory P-states\]](#)) and a timing register does not have per memory P-state contexts, BIOS must evaluate the minimum value for each frequency and choose the most pessimistic value for all frequencies to program into the register. These parameters are:

- [D18F2x20C\\_dct\[0\]\\_mp\[1:0\]\[Tcwl\]](#): CAS write latency
- [D18F2x220\\_dct\[0\]\[Tmrd\]](#): MRS command cycle time
- [D18F2x220\\_dct\[0\]\[Tmod\]](#): MRS command recovery time
- [D18F2x224\\_dct\[0\]\[Tzqcs\]](#): Short calibration command recovery time
- [D18F2x224\\_dct\[0\]\[Tzqoper\]](#): Long calibration command recovery time
- [D18F2x248\\_dct\[0\]\\_mp\[1:0\]\[Txpdll\]](#): Exit precharge power down (with DLL frozen) to command delay.
- [D18F2x248\\_dct\[0\]\\_mp\[1:0\]\[Txp\]](#): Exit precharge power down to command delay.
- [D18F2x24C\\_dct\[0\]\[Tcksrx\]](#): Clock stable to self refresh exit delay
- [D18F2x24C\\_dct\[0\]\[Tcksre\]](#): Self refresh entry to clock removal delay
- [D18F2x24C\\_dct\[0\]\[Tckesr\]](#): Self refresh entry to command delay
- [D18F2x24C\\_dct\[0\]\[Tpd\]](#): Power down entry to exit delay. BIOS may increase this value above the JEDEC minimum for certain power down modes.

### 2.9.7.6 Non-SPD ROM-Based Configuration

There are several DRAM timing parameters and DCT configurations that need to be programmed for optimal memory performance. These values are not derived from the SPD ROM. Several of these timing parameters are functions of other configuration values. These interdependencies must be considered when programming values into several DCT register timing fields. The factors to consider when specifying a value for a specific non-SPD timing parameter are:

- Training delay values. See [2.9.7.9 \[DRAM Training\]](#).
- Read and write latency differences.
- The phy's idle clock requirements on the data bus.
- DDR3 ODT timing requirements.
- NCLK frequency
- MEMCLK frequency

The following sub-sections describe how BIOS programs each non-SPD related timing field to a recommended minimum timing value with respect to the above factors.

The following terms are defined to simplify calculations and are calculated in MEMCLKs:

- Latency Difference (LD) = [D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Tcl\]](#) - [D18F2x20C\\_dct\[0\]\\_mp\[1:0\]\[Tcwl\]](#).
  - These equations assume [D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Tcl\]](#) >= [D18F2x20C\\_dct\[0\]\\_mp\[1:0\]\[Tcwl\]](#).
- Read ODT Delay (ROD) = MAX(0, [D18F2x240\\_dct\[0\]\\_mp\[1:0\]\[RdOdtOnDuration\]](#) - 6).

- Write ODT Delay (WOD) =  $\text{MAX}(0, \text{D18F2x240\_dct}[0]_{\text{mp}}[1:0][\text{WrOdtOnDuration}] - 6)$ .
- $\text{WrEarly} = \text{ABS}(\text{D18F2x20C\_dct}[0]_{\text{mp}}[1:0][\text{WrDqDqsEarly}]) / 2$

#### 2.9.7.6.1 TrdrdSdSc, TrdrdSdDc, and TrdrdDd (Read to Read Timing)

The optimal values for  $\text{D18F2x218\_dct}[0]_{\text{mp}}[1:0][\text{TrdrdSdSc}, \text{TrdrdSdDc}, \text{TrdrdDd}]$  are platform and configuration specific and should be characterized for best performance. Prior to DRAM training, BIOS should program these parameters to the largest defined value. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values:

- $\text{TrdrdSdSc}$  (in MEMCLKs) = 1.
- $\text{TrdrdSdDc}$  (in MEMCLKs) =  $\text{MAX}(\text{TrdrdSdSc}, 3 + (\text{IF}(\text{D18F2xA8\_dct}[0][\text{PerRankTimingEn}]) \text{ THEN } \text{CEIL}(\text{CDD}_{\text{TrdrdSdDc}} / 2 + 0.5) \text{ ELSE } 0 \text{ ENDIF}))$ .
- $\text{TrdrdDd}$  (in MEMCLKs) =  $\text{MAX}(\text{TrdrdSdDc}, \text{ROD} + 3, \text{CEIL}(\text{CDD}_{\text{TrdrdDd}} / 2 + 3.5))$ .

The Critical Delay Difference (CDD) is the largest delay difference of the channel.

- Each delay difference is  $\text{D18F2x9C\_x0000\_00}[2A:10]_{\text{dct}}[0]_{\text{mp}}[1:0][\text{DqsRcvEnGrossDelay}]$  minus  $\text{D18F2x9C\_x0000\_00}[2A:10]_{\text{dct}}[0]_{\text{mp}}[1:0][\text{DqsRcvEnGrossDelay}]$ .
- For  $\text{CDD}_{\text{TrdrdSdDc}}$ , the subtraction terms are the delays of different chip selects within the same DIMM within the same byte lane.
- For  $\text{CDD}_{\text{TrdrdDd}}$ , the subtraction terms are the delays of different DIMMs within the same byte lane.

#### 2.9.7.6.2 TwrwrSdSc, TwrwrSdDc, TwrwrDd (Write to Write Timing)

The optimal values for  $\text{D18F2x214\_dct}[0]_{\text{mp}}[1:0][\text{TwrwrSdSc}, \text{TwrwrSdDc}, \text{TwrwrDd}]$  are platform and configuration specific and should be characterized for best performance. Prior to DRAM training, BIOS should program these parameters to the largest defined value. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values:

- $\text{TwrwrSdSc}$  (in MEMCLKs) = 1.
- $\text{TwrwrSdDc}$  (in MEMCLKs) =  $\text{MAX}(\text{TwrwrSdSc}, \text{WOD} + 3, 3 + (\text{IF}(\text{D18F2xA8\_dct}[0][\text{PerRankTimingEn}]) \text{ THEN } \text{CEIL}(\text{CDD}_{\text{TwrwrSdDc}} / 2 + 0.5) \text{ ELSE } 0 \text{ ENDIF}))$ .
- $\text{TwrwrDd}$  (in MEMCLKs) =  $\text{MAX}(\text{TwrwrSdDc}, \text{WOD} + 3, \text{CEIL}(\text{CDD}_{\text{TwrwrDd}} / 2 + 3.5))$ .

The Critical Delay Difference (CDD) is the largest delay difference of the channel.

- Each delay difference is  $\text{D18F2x9C\_x0000\_00}[4A:30]_{\text{dct}}[0]_{\text{mp}}[1:0][\text{WrDqsGrossDly}]$  minus  $\text{D18F2x9C\_x0000\_00}[4A:30]_{\text{dct}}[0]_{\text{mp}}[1:0][\text{WrDqsGrossDly}]$ .
- For  $\text{CDD}_{\text{TwrwrSdDc}}$ , the subtraction terms are the delays of different chip selects within the same DIMM within the same byte lane.
- For  $\text{CDD}_{\text{TwrwrDd}}$ , the subtraction terms are the delays of different DIMMs within the same byte lane.

#### 2.9.7.6.3 Twrrd (Write to Read DIMM Termination Turn-around)

The optimal value for  $\text{D18F2x218\_dct}[0]_{\text{mp}}[1:0][\text{Twrrd}]$  is platform and configuration specific and should be characterized for best performance. Prior to DRAM training, BIOS should program these parameters to the largest defined value. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values:

- $\text{Twrrd}$  (in MEMCLKs) =  $\text{MAX}(1, \text{MAX}(\text{WOD}, \text{CEIL}(\text{CDD}_{\text{Twrrd}} / 2 + 2 - \text{WrEarly})) - \text{LD} + 3)$ .

The Critical Delay Difference (CDD) is the largest delay difference of the channel.

- Each delay difference is  $\text{D18F2x9C\_x0000\_00}[4A:30]_{\text{dct}}[0]_{\text{mp}}[1:0][\text{WrDqsGrossDly}]$  minus

[D18F2x9C\\_x0000\\_00\[2A:10\]\\_dct\[0\]\\_mp\[1:0\]\[DqsRcvEnGrossDelay\]](#).

- For  $CDD_{TrwtTO}$ , the subtraction terms are the delays of different chip selects within the same byte lane.

#### 2.9.7.6.4 TrwtTO (Read-to-Write Turnaround for Data, DQS Contention)

The optimal value for [D18F2x21C\\_dct\[0\]\\_mp\[1:0\]\[TrwtTO\]](#) is platform and configuration specific and should be characterized for best performance. Prior to DRAM training, BIOS should program this parameter to the largest defined value. After DRAM training, BIOS should use the guidelines below to configure the recommended platform generic timing values after DDR training is complete:

- $TrwtTO$  (in MEMCLKs) =  $MAX(ROD, CEIL(CDD_{TrwtTO} / 2 + WrEarly)) + LD + 3$ .
  - If 1 DIMM/ch, substitute  $ROD = 0$  in the above equation. Assumes no DIMM ODT switching occurs.

The Critical Delay Difference (CDD) is the largest delay difference of the channel.

- Each delay difference is [D18F2x9C\\_x0000\\_00\[2A:10\]\\_dct\[0\]\\_mp\[1:0\]\[DqsRcvEnGrossDelay\]](#) minus [D18F2x9C\\_x0000\\_00\[4A:30\]\\_dct\[0\]\\_mp\[1:0\]\[WrDqsGrossDly\]](#).
- For  $CDD_{TrwtTO}$ , the subtraction terms are the delays of all chip selects within the same byte lane.

#### 2.9.7.6.5 DRAM ODT Control

BIOS configures the DIMM ODT behavior per chip select according to the DIMM population. The ODT pin patterns for reads and writes are programmed using [D18F2x\[234:230\]\\_dct\[0\]](#) and [D18F2x\[23C:238\]\\_dct\[0\]](#), respectively.

BIOS also configures the ODT pin pattern used during write leveling by programming [D18F2x9C\\_x0000\\_0008\\_dct\[0\]\\_mp\[1:0\]\[WrLvOdtEn, WrLvOdt\]](#). BIOS programs  $WrLvOdt$  with the [D18F2x\[23C:238\]\\_dct\[0\]](#) value provided for writes to the rank targeted by training. See 2.9.7.9.1 [Write Levelization Training].

#### 2.9.7.6.6 DRAM Address Timing and Output Driver Compensation Control

This section describes the settings required for programming the timing on the address pins, the CS/ODT pins, and the CKE pins. The following tables document the address timing and output driver settings on a per channel basis for DDR3. These tables document the optimal settings for motherboards which meet the relevant AMD socket motherboard design guidelines. See [2.9.2 \[DCT Frequency Support\]](#) for an overview of the DIMM and memory bus speed support.

When POdtOff=0, in all cases the processor ODT is off for writes and is on for reads.

Table 42: BIOS recommendations for SlowAccessMode, POdtOff, Addr/Cmd Timings and Output Driver Control **UDIMM** FT3 package

### 2.9.7.7 DCT Training Specific Configuration

The DCT requires certain features be disabled during DRAM device initialization and training. BIOS should program the registers in [Table 47](#) before DRAM device initialization and training. For normal operation, BIOS programs the recommended values if provided in [Table 47](#). BIOS must quiesce all other forms of DRAM traffic on the channel being trained. See [2.9.7 \[DCT/DRAM Initialization and Resume\]](#).

**Table 47: DCT Training Specific Register Values**

| Register                                                                                                                                                                                                                                                                            | Training | Normal Operation                                    |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------|-----------------------------------------------------|
| D18F2x78_dct[0][AddrCmdTriEn]                                                                                                                                                                                                                                                       | 0        | 1                                                   |

### 2.9.7.8 DRAM Device and Controller Initialization

BIOS initializes the DRAM devices and the controller using either a hardware or a software controlled sequence. Hardware init is supported for verification only. See [2.10.8.8.1 \[Hardware DDR3 Device Initialization\]](#) and [2.9.7.8.1 \[Software DDR3 Device Initialization\]](#).

BIOS must observe additional requirements for changing the PLL frequency when setting D18F2x90\_dct[0][InitDrum] or D18F2x7C\_dct[0][EnDrumInit]. See [2.9.7.4.2 \[DRAM Channel Frequency](#)

Change].

DRAM initialization is complete after the value of `D18F2x90_dct[0][InitDram]` transitions from 1 to 0 in the hardware-controlled sequence or the value of `D18F2x7C_dct[0][EnDramInit]` is written by BIOS from 1 to 0 in the software-controlled sequence.

### 2.9.7.8.1 Software DDR3 Device Initialization

BIOS should apply the following procedure to each DCT to initialize the DDR3 DIMMs on the channel. This procedure should be run only when booting from an unpowered state (ACPI S4, S5 or G3; not S3, suspend to RAM).

1. Program `D18F2x7C_dct[0][EnDramInit]` = 1.
2. Wait 200 us.
3. Program `D18F2x7C_dct[0][DeassertMemRstX]` = 1.
4. Wait 500 us.
5. Program `D18F2x7C_dct[0][AssertCke]` = 1.
6. Wait 360 ns.
7. Send MRS(2).
8. Send MRS(3). Ordinarily at this time, `MrsAddress[2:0]` = 000b.
9. Send MRS(1) with `MrsAddress[7]` = 0 (write leveling disabled).
10. Send MRS(0) with `MrsAddress[8]` = 1 (reset the DLL).
11. Send two ZQCL commands.
- BIOS instructs the DCT to send a ZQCL command by programming `D18F2x7C_dct[0]` as follows:
  - Program `MrsAddress[10]` = 1.
  - Program `SendZQCmd` = 1.
  - Wait for `SendZQCmd` = 0.
  - Wait 512 MEMCLKs.
12. Program `D18F2x7C_dct[0][EnDramInit]` = 0.
13. Program `D18F2x2E8_dct[0]_mp[1:0]`, `D18F2x2EC_dct[0]_mp[1:0]` with a copy of the mode register data sent in the steps above, except with `MR0[DLL]` = 0 (Do not reset the DRAM DLL with a memory P-state change).

#### 2.9.7.8.1.1 DDR3 MR Initialization

BIOS instructs the DCT to send MRS commands by programming `D18F2x7C_dct[0]` as follows:

1. Program `MrsBank` and `MrsAddress` as specified below:
  - `MrsBank[2:0]` = BA2:BA0.
  - `MrsAddress[15:0]` = A15:A0.
  - BIOS may need to remap bits, see also `D18F2x[5C:40]_dct[0][OnDimmMirror]`.
  - Set all other bits in `MrsAddress` to zero. BIOS should write reserved fields as 0.
2. Program `MrsChipSel` as appropriate.
3. Program `SendMrsCmd` = 1.
4. Wait for `SendMrsCmd` = 0.

**MR0 DDR3 MR0**

Table 48: BIOS Recommendations for MR0[WR]

| Condition                     | MR0     |
|-------------------------------|---------|
| D18F2x22C_dct[0]_mp[1:0][Twr] | WR[3:0] |

### 2.9.7.9 DRAM Training

This section describes detailed methods used to train the processor DDR interface to DRAM for optimal functionality and performance. DRAM training is performed by BIOS after initializing the DRAM controller. See [2.9.7.8 \[DRAM Device and Controller Initialization\]](#).

Some of the DRAM training steps described in this section require two passes if the target MEMCLK frequency is greater than 333 MHz. For optimal software performance, software may defer the second pass (at target MEMCLK frequency) for each training step until after the first pass (at lowest supported frequency) of all other training steps are complete. See [D18F2x94\\_dct\[0\]\[MemClkFreq\]](#).

Product specific training requirements are as follows:

- Program [D18F2x9C\\_x0000\\_0008\\_dct\[0\]\\_mp\[1:0\]\[TrNibbleSel\]](#)=0.
- Program [D18F2xA8\\_dct\[0\]\[PerRankTimingEn\]](#)=1.

See [2.9.7.7 \[DCT Training Specific Configuration\]](#) for additional training requirements.

In the following subsections, lane is used to describe an 8-bit wide data group, each with its own timing control.

#### 2.9.7.9.1 Write Levelization Training

Write levelization involves using the phase recovery engine in the phy to detect the edge of DQS with respect to the memory clock on the DIMM for write accesses to each lane.

Training is accomplished on a per channel, per rank basis. If the target frequency is greater than 333 MHz then BIOS performs two passes; otherwise, only one pass is required. See [2.9.7.4.2 \[DRAM Channel Frequency Change\]](#).

- Pass 1: Configure the memory subsystem for 333 MHz MEMCLK frequency.
- Pass 2: Configure the memory subsystem for the target MEMCLK frequency. BIOS must reconfigure the phy and the DRAM devices to the new target frequency.

The following describes the steps used for each pass of write levelization training for each channel:

For each rank:

1. Prepare the DIMMs for write levelization using DDR3-defined MR commands.
  - A. Configure the output driver and on-die termination of the target DIMM as follows:
    - For the target rank of the target DIMM, enable write leveling mode and enable the output driver.
    - For all other ranks of the target DIMM, enable write leveling mode and disable the output driver.

- For two or more DIMMs per channel, program Rtt\_Nom of the target rank to the corresponding specified Rtt\_Wr termination. Otherwise, configure Rtt\_Nom of the target DIMM as normal. See 2.9.7.6.6 [DRAM Address Timing and Output Driver Compensation Control].
- B. Configure Rtt\_Nom on the non-target DIMMs as normal. See 2.9.7.6.6 [DRAM Address Timing and Output Driver Compensation Control].
- 2. Wait 40 MEMCLKs to satisfy DDR3-defined internal DRAM timing parameters tWLMRD, tWLODEN, and tWLDQSEN.
- 3. Configure the phy for write levelization training:
  - A. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][WrtLvTrEn]=0.
  - B. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][TrChipSel] to specify the target rank to be trained.
  - C. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][WrLvOdt] to the proper ODT settings for the current memory subsystem configuration. See 2.9.7.6.5 [DRAM ODT Control].
  - D. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][WrLvOdtEn]=1.
  - E. MFENCE.
  - F. Wait 10 MEMCLKs to allow for ODT signal settling.
  - G. For each lane program an initial value to registers D18F2x9C\_x0000\_00[52:50]\_dct[0] to set the gross and fine delay. See 2.9.7.9.1.1 [Write Leveling Seed Value].
- 4. Perform write leveling of the devices on the DIMM:
  - A. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][WrtLvTrEn]=1.
  - B. MFENCE.
  - C. Wait 200 MEMCLKs.
  - D. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][WrtLvTrEn]=0.
  - E. Read from registers D18F2x9C\_x0000\_00[52:50]\_dct[0] to get the gross and fine delay settings for the target DIMM and save these values.
- 5. Disable write levelization training so that the phy stops driving write levelization ODT.
  - A. Program D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0][WrLvOdtEn]=0.
  - B. MFENCE.
  - C. Wait 10 MEMCLKs to allow for ODT signal settling.
- 6. Program the target DIMM back to normal operation by configuring the following:
  - A. Configure all ranks of the target DIMM for normal operation.
  - B. Enable the output drivers of all ranks of the target DIMM.
  - C. For a two or more DIMM system, program the Rtt\_Nom value for the target DIMM to the normal operating termination.

For each rank:

- BIOS calculates and programs the final saved gross and fine delay values for each lane into D18F2x9C\_x0000\_00[4A:30]\_dct[0]\_mp[1:0] [DRAM DQS Write Timing].
  - $WrDqsFineDly = PhRecFineDly$ .
  - $GrossDly = SeedGross + PhRecGrossDly - SeedPreGross$ .
    - The Critical Gross Delay (CGD) is the minimum GrossDly of all byte lanes and all DIMMs.
    - If  $(CGD < 0)$  Then
      - $D18F2x20C\_dct[0]_mp[1:0][WrDqDqsEarly] = ABS(CGD)$
      - $WrDqsGrossDly = GrossDly + WrDqDqsEarly$
    - Else
      - $D18F2x20C\_dct[0]_mp[1:0][WrDqDqsEarly] = 1$ .
      - $WrDqsGrossDly = GrossDly + 1$ .

### 2.9.7.9.1.1 Write Leveling Seed Value

The seed value for pass 1 of write leveling is design and platform specific. The seed value represents the actual clock delay and is platform dependent. The platform vendor may need to characterize and adjust this value for

proper write levelization training. The seed delay value must fall within +/- 1/2 MEMCLK, including silicon PVT margin and jitter of the measured clock delay.

1. Calculate the total seed based on the following:
  - Pass 1: SeedTotal = configuration specific seed value found in [Table 51](#).
  - Pass N:
    - SeedTotalPreScaling = the total delay values obtained from the previous (N-1) pass of write levelization training.
      - Write Leveling Total Delay = `D18F2x9C_x0000_00[4A:30]_dct[0]_mp[1:0][WrDqsGrossDly, WrDqsFineDly] - (0x20 * D18F2x20C_dct[0]_mp[1:0][WrDqDqsEarly])`
    - SeedTotal = SeedTotalPreScaling\*(target frequency)/(frequency from previous pass).
2. SeedGross = SeedTotal DIV 32.
3. SeedFine = SeedTotal MOD 32.
4. If (SeedGross is odd)
  - then SeedPreGross = 1
  - else SeedPreGross = 2. Only LSB is used to effect starting PRE gross delay. Setting MSB allows the phase recovery engine a positive and negative adjustment range.
5. Program `D18F2x9C_x0000_00[52:50]_dct[0][PhRecFineDly]` = SeedFine.
6. Program `D18F2x9C_x0000_00[52:50]_dct[0][PhRecGrossDly]` = SeedPreGross.

**Table 51: DDR3 Write Leveling Seed Values**

| DIMM Type              | Seed Value <sup>1</sup> |
|------------------------|-------------------------|
| Solder-down DRAM       | 0Eh                     |
| SODIMM                 | 0Eh                     |
| UDIMM                  | 15h                     |
| 1. DDR3-667 (333 MHz). |                         |

### 2.9.7.9.2 DQS Receiver Enable Training

Receiver enable delay training is used to dynamically determine the optimal delay value for `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0]` [DRAM DQS Receiver Enable Timing]. The optimal DQS receiver enable delay value is platform and load specific, and occurs in the middle of a received read preamble. The timing of the preamble includes the inbound DQS propagation delay, which is unknown by BIOS. The training for delay values involves:

1. Configuring the phy PRE for an initial expected phase value (seed).
2. Generating a stream of read DQS edges from the DRAM by issuing multiple read commands.
3. The phy PRE determining the phase between the received DQS edges and a reference clock.
4. Calculating a final delay value for enabling receivers during normal read operations using the phase determined by the phy PRE.

Prior to DQS Receiver Enable Training, BIOS must program `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency]` based on the seeded value of `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0]`. See 2.9.7.9.5 [Calculating MaxRdLatency].

Training is accomplished on a per channel, per rank basis. If the target frequency is greater than 333 MHz then BIOS performs two passes; otherwise only one pass is required. See 2.9.7.4.2 [DRAM Channel Frequency

Change].

- Pass 1: Configure the memory subsystem for 333 MHz MEMCLK frequency.
- Pass 2: Configure the memory subsystem for the target MEMCLK frequency. BIOS must reconfigure the phy and the DRAM devices to the new target frequency.

The following describes the steps used for each pass of receiver enable training for each channel:

For each rank:

1. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][TrChipSel]` to specify the target rank to be trained.
2. For each lane program an initial value to registers `D18F2x9C_x0000_00[52:50]_dct[0]` to set the gross and fine delay as specified in 2.9.7.9.2.1 [DQS Receiver Enable Training Seed Value].
3. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][DqsRcvTrEn]=1`.
4. Issue 192 read requests to the target rank. See 2.9.8 [Continuous Pattern Generation].
5. Program `D18F2x9C_x0000_0008_dct[0]_mp[1:0][DqsRcvTrEn]=0`.
6. Read `D18F2x9C_x0000_00[52:50]_dct[0][PhRecGrossDly, PhRecFineDly]` to get the gross and fine delay values for each lane.
7. For each lane, calculate and program the corresponding receiver enable delay values for `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay, DqsRcvEnFineDelay]`. Save the result for use later.
  - $DqsRcvEnFineDelay = PhRecFineDly$ .
  - $DqsRcvEnGrossDelay = SeedGross + PhRecGrossDly - SeedPreGross + 1$ . “+1” to add 1 UI to enable the receiver in the mid point of preamble.

#### 2.9.7.9.2.1 DQS Receiver Enable Training Seed Value

The seed value for pass 1 of receiver enable delay training is design and platform specific and should be determined by characterization for best performance. The seed value represents the total delay from a reference point to the first expected rise edge of DQS on a read CAS measured at the processor pins, in 1 UI/32 increments. The reference point is defined as the clock in which CAS is asserted + CL - 1.

The following steps are taken to determine the seed values needed to program the DRAM Phase Recovery Control Registers:

For each pass and each lane:

1. Calculate the total seed based on the following:
  - Pass 1:  $SeedTotal = \text{The seed value found in Table 52} + \text{the total delay values obtained from the first pass of write levelization training. See 2.9.7.9.1 [Write Levelization Training].}$ 
    - $\text{Write Leveling Total Delay} = D18F2x9C\_x0000\_00[4A:30]_dct[0]_mp[1:0][WrDqsGrossDly, WrDqsFineDly] - (0x20 * D18F2x20C\_dct[0]_mp[1:0][WrDqDqsEarly])$
  - Pass N:
    - $RegisterDelay = 0$
    - $SeedTotalPreScaling = (\text{the total delay values in } D18F2x9C\_x0000\_00[2A:10]_dct[0]_mp[1:0] \text{ from the previous (N-1) pass of training}) - RegisterDelay - 20h$ . Stored value was adjusted 1 UI to enable the receiver in the mid point of preamble. Subtract 1 UI to get back to the preamble left edge.
    - $SeedTotal = RegisterDelay + FLOOR(SeedTotalPreScaling * (\text{target frequency}) / (\text{frequency from previous pass}))$ .
2.  $SeedGross = SeedTotal \text{ DIV } 32$ .
3.  $SeedFine = SeedTotal \text{ MOD } 32$ .
4. If (SeedGross is odd)  
then  $SeedPreGross = 1$

else SeedPreGross = 2. Only LSB is used to effect starting PRE gross delay. Setting MSB allows the phase recovery engine a positive and negative adjustment range.

5. Program `D18F2x9C_x0000_00[52:50]_dct[0][PhRecFineDly] = SeedFine`.
6. Program `D18F2x9C_x0000_00[52:50]_dct[0][PhRecGrossDly] = SeedPreGross`.
7. Program `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay] = IF ((NBCOF / DdrRate < 1) && (D18F2x200_dct[0]_mp[1:0][Tcl]=5) && (SeedGross<1) THEN 1 ELSE SeedGross ENDIF`.

**Table 52. DDR3 DQS Receiver Enable Training Seed Values**

| DIMM Type             | Seed Value <sup>1</sup> |
|-----------------------|-------------------------|
| Solder-down DRAM      | Char.Temp:20h           |
| SODIMM                | Char.Temp:32h           |
| UDIMM                 | Char.Temp:32h           |
| 1. DDR3-667 (333 MHz) |                         |

### 2.9.7.9.3 DQS Receiver Enable Cycle Training

Receiver enable delay cycle training is used to train the gross delay settings of `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0]` to the middle of the received read preamble using the phy PRE phase results.

For each rank and lane:

1. Program `D18F2x9C_x0D0F_0[F,8:0]30_dct[0][BlockRxDqsLock] = 1`.
2. `RxEnOrig = D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay, DqsRcvEnFineDelay]` result from 2.9.7.9.2 [DQS Receiver Enable Training]. (expected mid-preamble position based on the seed)
3. `RxEnOffset = MOD(RxEnOrig + 10h, 40h)` (offset by 1/4 MEMCLK, keep only the phase)
4. For each `DqsRcvEn` value beginning from `RxEnOffset` incrementing by 1 MEMCLK:
  - A. Program `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay, DqsRcvEnFineDelay]` with the current value.
  - B. Perform 2.9.7.9.4 [DQS Position Training].
    - Record the result for the current `DqsRcvEn` setting as a pass or fail depending if a data eye is found.
5. Process the array of results and determine a pass-to-fail transition. (Consider a pass in the last array element as a pass-to-fail transition)
  - A. `DqsRcvEnCycle` = the total delay value of the pass result.
  - B. Program `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay, DqsRcvEnFineDelay] = DqsRcvEnCycle - 10h`. (subtract 1/4 MEMCLK to place the final `DqsRcvEn` mid-preamble)
6. Program `D18F2x9C_x0D0F_0[F,8:0]30_dct[0][BlockRxDqsLock] = 0`.

### 2.9.7.9.4 DQS Position Training

DQS position training is used to place the DQS strobe in the center of the read DQ data eye and to center the write DQ data eye across the write DQS strobe. Determining the correct DRAM DQS and DQ delay settings for both reads and writes is conducted by performing a two dimensional search of the delay settings found in `D18F2x9C_x0000_0[3:0]0[7:5]_dct[0]_mp[1:0]` [DRAM Read DQS Timing] and `D18F2x9C_x0000_0[3:0]0[3:1]_dct[0]_mp[1:0]` [DRAM Write Data Timing].

Training is accomplished on a per channel, per rank, and per lane basis.

For DQS position training, BIOS generates a training pattern using continuous read or write data streams. A 2k-bit-time training pattern is recommended for optimal results. To achieve this, BIOS programs `D18F2x260_dct[0][CmdCount] = 256`, `D18F2x250_dct[0][CmdTgt]=01b`, and `D18F2x25[8,4]_dct[0]` to access two different banks of the same CS. See 2.9.8 [Continuous Pattern Generation].

Prior to DQS position training, BIOS must program `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency]` based on the current greatest value of `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0]`. See 2.9.7.9.5 [Calculating MaxRdLatency].

The following describes the steps used for DQS position training for each channel:

- Program `D18F2x9C_x0D0F_0[F,8:0]1F_dct[0]_mp[1:0]` for all lanes.
  - `RxDqInsDly = 0`. This could be reset from a prior frequency step. Start out with zero added delay for first try.

For each rank and lane:

1. Select a 64 byte aligned test address.
2. For each write data delay value in `D18F2x9C_x0000_0[3:0]0[3:1]_dct[0]_mp[1:0]` from Wr-DQS to Wr-DQS plus 1 UI, using the Wr-DQS delay value found in 2.9.7.9.1 [Write Levelization Training]:
  - Program the write data delay value for the current lane.
  - Write the DRAM training pattern to the test address.
3. For each read DQS delay value in `D18F2x9C_x0000_0[3:0]0[7:5]_dct[0]_mp[1:0]` from 0 to 1 UI:
  - Program the read DQS delay value for the current lane.
  - Read the DRAM training pattern from the test address.
  - Record the result for the current settings as a pass or fail depending if the pattern is read correctly.
  - Process the array of results and determine the longest string of consecutive passing read DQS delay values.
    - If the read DQS delay results for the current lane contain three or more consecutive passing delay values, then program `D18F2x9C_x0000_0[3:0]0[7:5]_dct[0]_mp[1:0]` with the average value of the smallest and largest delay values in the string of consecutive passing results.
    - If the average value of passing read DQS delay for the lane is negative, then adjust the input receiver DQ delay in `D18F2x9C_x0D0F_0[F,8:0]1F_dct[0]_mp[1:0][RxDqInsDly]` for the lane as follows:
      - IF (`RxDqInsDly < 3`) THEN increment `RxDqInsDly` and repeat step 3 above for all ranks and lanes; See note below.
      - ELSE program the read DQS delay for the lane with a value of zero. BIOS should also flag an error message for debug analysis.
      - ENDIF.
  - 4. Process the array of results and determine the longest string of consecutive passing write data delay values for the read DQS delay value found in the step above.
    - If the write data delay results for the current lane contain three or more consecutive passing delay values, then program `D18F2x9C_x0000_0[3:0]0[3:1]_dct[0]_mp[1:0]` with the average value of the smallest and largest delay values in the string of consecutive passing results.

See Figure 2.

### Figure 2: DQS Position Training Example Results

In some cases, a non-zero process, voltage, and temperature dependent insertion delay is added to the DLL programmed read DQS delay. This has the effect of sampling data later than intended and can result in missing the left edge of the passing region when sweeping from 0 to 1 UI because a read DQS delay value of 0 is already in the passing region. Since DQS is periodic, BIOS can recover the missing information by adjusting the algorithm described above to analyze both the in phase data and the data shifted by one bit time at each step of the read DQS delay sweep. See [D18F2x268\\_dct\[0\]\[NibbleErrSts\]](#) and [D18F2x26C\\_dct\[0\]\[NibbleErr180Sts\]](#).

As shown in Figure 3, for each delay setting BIOS records a passing result of  $P_\Phi$  for the data comparison shifted by one bit time if the data at bit times  $N=0, 1, \dots, 6$ , is read correctly when compared against the data written at bit times  $N=1, 2, \dots, 7$ . In the array of results, these passing values make up the left piece of information that had been lost due to insertion delay. In order to process the array of results, BIOS calculates the read DQS delay value for a  $P_\Phi$  result as  $RdDqsTimeByte$  minus 1 UI.

**Figure 3: DQS Position Training Insertion Delay Recovery Example Results**

### 2.9.7.9.5 Calculating MaxRdLatency

The MaxRdLatency value determines when the memory controller can receive incoming data from the DCTs. Calculating MaxRdLatency consists of summing all the synchronous and asynchronous delays in the path from the processor to the DRAM and back at a given MEMCLK frequency. BIOS incrementally calculates the MaxRdLatency and then finally programs the value into `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency]`.

The following steps describe the algorithm used to compute `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency]` used for DRAM training. P, N, and T are used as a temporary placeholders for the incrementally summed value.

1.  $P = N = T = 0$
2. If (`D18F2x9C_x0000_0004_dct[0]_mp[1:0][AddrCmdSetup] = 0` & `D18F2x9C_x0000_0004_dct[0]_mp[1:0][CsOdtSetup] = 0` & `D18F2x9C_x0000_0004_dct[0]_mp[1:0][CkeSetup] = 0`)  
then  $P = P + 1$   
else  $P = P + 2$
3.  $P = P + (8 - \text{D18F2x210\_dct[0]_nbp[3:0][RdPtrInit]})$ 
  - Worst case in real silicon. See step 4.
4.  $P = P + \text{NumPclks}$ 
  - NumPclks = 6
5.  $P = P + (2 * (\text{D18F2x200\_dct[0]_mp[1:0][Tcl]} - 1 \text{ clocks}))$
6.  $P = P + \text{CEIL}(\text{MAX}(\text{D18F2x9C\_x0000\_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay, DqsRcvEnFineDelay]} + \text{D18F2x9C\_x0000\_0[3:0]0[7:5]_dct[0]_mp[1:0][RdDqsTime]} \text{ PCLKs})) + 1$ 
  - Prior to DQS position training, use maximum value for RdDqsTime.
7. If (`NclkFreq/MemClkFreq < 2`) then  $P = P + 4.5$   
Else  $P = P + 2.5$
8.  $T = T + 1050 \text{ ps}$
9.  $N = (P / (\text{MemClkFreq} * 2) + T) * \text{NclkFreq}$ ; Convert from PCLKs plus time to NCLKs.
  - See `D18F5x16[C:0][NbDid, NbFid]` and `D18F2x94_dct[0][MemClkFreq]`.
10. `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency] = CEIL(N) + NumNclks`
  - NumNclks = 1

#### 2.9.7.9.5.1 MaxRdLatency Training

After DRAM DQS receiver enable training, BIOS optimizes `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency]` using the following algorithm. For MaxRdLatency training, BIOS generates a training pattern using continuous read or write data streams. See 2.9.8 [Continuous Pattern Generation].

For each channel:

1. Calculate a starting MaxRdLatency delay value by executing the steps in 2.9.7.9.5, excluding steps 4, 7, 8, and 10. It is expected that the first value will result in a test fail.
2. Select 32 64-byte aligned test addresses associated with the rank that has the worst case (`D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0][DqsRcvEnGrossDelay, DqsRcvEnFineDelay] + D18F2x9C_x0000_0[3:0]0[7:5]_dct[0]_mp[1:0][RdDqsTime]`) register setting.
3. Write the DIMM test addresses with the training pattern.
4. For each MaxRdLatency value incrementing from the value calculated in step 1:
  - A. Program `D18F2x210_dct[0]_nbp[3:0][MaxRdLatency]` with the current value.
  - B. Read the DIMM test addresses.
  - C. Compare the values read against the pattern written.
    - If the pattern is read correctly, go to step 5.
  - D. Program `D18F2x9C_x0000_0050_dct[0]=00000000h` to reset the RcvFifo.

5. Program `D18F2x210_dct[0]_nbp[3:0]`[MaxRdLatency] = CEIL(current value + 1 NCLK + (IF (Verification) THEN 1.0 MEMCLK ELSE 1.5 MEMCLK ENDIF) + IF (NclkFreq/MemClkFreq < 2) THEN 1.0 MEMCLK ELSE 0 ENDIF) .

### 2.9.7.10 DRAM Phy Power Savings

For power savings, BIOS should perform the following actions for each channel:

1. Program `D18F2x88_dct[0]`[MemClkDis] to disable unused MEMCLK pins.
2. Program `D18F2x9C_x0D0F_2[F,2:0]30_dct[0]`[PwrDn] for unused MEMCLK pairs.
3. Program `D18F2x9C_x0D0F_0[F,8:0]30_dct[0]`[PwrDn] to disable the ECC lane if `D18F2x90_dct[0]`[DimmEccEn]==0.
4. Program `D18F2x9C_x0000_000C_dct[0]`[CKETri, ODTTri, ChipSelTri] to disable unused pins.
5. Per byte, if none of `D18F2x9C_x0D0F_0[F,8:0][17:14]`[EarlyLateU[3:0]] is set to 1, then Program `D18F2x9C_x0D0F_0[F,8:0]13_dct[0]_mp[1:0]`[DlIDisEarlyU] = 1.
6. Per byte, if none of `D18F2x9C_x0D0F_0[F,8:0][17:14]`[EarlyLateL[3:0]] is set to 1, then Program `D18F2x9C_x0D0F_0[F,8:0]13_dct[0]_mp[1:0]`[DlIDisEarlyL] = 1.
7. `D18F2x9C_x0D0F_812F_dct[0]`[PARTri] = 1.
8. `D18F2x9C_x0D0F_812F_dct[0]`[Add17Tri, Add16Tri] = { 1b, 1b }
9. Program `D18F2x9C_x0D0F_0[F,8:0]10_dct[0]_mp[1:0]`[EnRxPadStandby] = IF (`DdrRate` <= 1600) THEN 1 ELSE 0 ENDIF.
10. Program `D18F2x9C_x0000_000D_dct[0]_mp[1:0]` as follows:
  - If (`DdrRate` <= 1600) TxMaxDurDlINoLock = RxMaxDurDlINoLock = 8h  
else TxMaxDurDlINoLock = RxMaxDurDlINoLock = 7h.
  - TxCPUUpdPeriod = RxCPUUpdPeriod = 011b.
  - TxDLLWakeUpTime = RxDLLWakeUpTime = 11b.
11. Program `D18F2x9C_x0D0F_0[F,8:0]1C_dct[0]_mp[1:0]` as follows:
  - If `D18F2x90_dct[0]`[DimmEccEn] Numlanes = 9 Else Numlanes = 8.
  - If (`DdrRate` >= 1866) DllWakeTime = 1 Else DllWakeTime = 0.
  - Let MaxRxStggrDly = ((Tcl-1)\*2) + MIN(DqsRcvEnGrossDelay for all byte lanes) - 6.
    - See `D18F2x9C_x0000_00[2A:10]_dct[0]_mp[1:0]`.
  - Let (real) dRxStggrDly = (MaxRxStggrDly - DllWakeTime) / (Numlanes - 1).
  - For each byte lane in the ordered sequence below, program `RxDllStggrDly[5:0]` = an increasing value, starting with 0 for the first byte lane in the sequence and increasing at a rate of dRxStggrDly for each subsequent byte lane.
    - Sequence: If `D18F2x90_dct[0]`[DimmEccEn] { 8, 4, 3, 5, 2, 6, 1, 7, 0 } else { 4, 3, 5, 2, 6, 1, 7, 0 }.
  - Let MaxTxStggrDly = MIN(((Tcwl-1)\*2) + MIN(WrDqsGrossDly for all byte lanes) - WrDqDqsEarly - 4, MaxRxStggrDly)
    - See `D18F2x9C_x0000_00[4A:30]_dct[0]_mp[1:0]`.
    - See `D18F2x20C_dct[0]_mp[1:0]`.
  - Let (real) dTxStggrDly = (MaxTxStggrDly - DllWakeTime) / (Numlanes - 1).
  - For each byte lane in the ordered sequence below, program `TxDllStggrDly[5:0]` = an increasing integer value, starting with 0 for the first byte lane in the sequence and increasing at a rate of dTxStggrDly for each subsequent byte lane.
    - Sequence: If `D18F2x90_dct[0]`[DimmEccEn] { 0, 7, 1, 6, 2, 5, 3, 4, 8 } else { 0, 7, 1, 6, 2, 5, 3, 4 }.
  - RxDllStggrEn = TxDllStggrEn = 1.
12. Program `D18F2x248_dct[0]_mp[1:0]` and then `D18F2x9C_x0D0F_0[F,8:0]13_dct[0]_mp[1:0]` as follows:
  - For M0 & M1 context program `RxChMntClkEn`=`RxSsbMntClkEn`=0.
13. Program `D18F2x9C_x0D0F_0[F,8:0]30_dct[0]`[TxPclkGateEn, PchgPdPClkGateEn, DataCtlPipePclkGateEn] = { 1, 1, 1 }.
14. Program `D18F2x9C_x0D0F_0[F,8:0]04_dct[0]_mp[1:0]`[TriDM] = IF (`DataMaskMbType` == 0) THEN 1 ELSE 0 ENDIF.

## 2.9.8 Continuous Pattern Generation

DRAM training relies on the ability to generate a string of continuous reads or writes between the processor and DRAM, such that worst case electrical interactions can be created. This section describes how these continuous strings of accesses may be generated.

### 2.9.8.1 DCT Training Pattern Generation (Reliable Read Write Mode)

DCT training pattern generation uses pattern generators in the DCT to generate controlled read and write traffic streams. During write pattern generation, data values based off of a deterministic pattern are burst to the DRAM interface. Conversely for reads, data bursts from the DRAM interface are compared against expected data values on a per nibble basis.

Two address modes are available for DRAM training pattern generation, as configured by [D18F2x250\\_dct\[0\]\[CmdTgt\]](#). For generating a stream of reads or writes to the same rank, address target A mode is used. To generate a stream of accesses to up to two different ranks, address target A and B mode is used.

An overview of the BIOS sequence to generate training patterns is as follows:

- Configure the DCT for pattern generation. See [2.9.7.7 \[DCT Training Specific Configuration\]](#).
- Ensure DIMMs are configured to support 8-beat bursts (BL8 or dynamic burst length on the fly).
- Wait for [D18F2x250\\_dct\[0\]\[CmdSendInProg\]](#) = 0.
- Program [D18F2x250\\_dct\[0\]\[CmdTestEnable\]](#) = 1.
- Send activate commands as appropriate. See [2.9.8.1.1 \[Activate and Precharge Command Generation\]](#).
- Send read or write commands as desired. See [2.9.8.1.2 \[Read and Write Command Generation\]](#).
- Send precharge commands as appropriate. See [2.9.8.1.1 \[Activate and Precharge Command Generation\]](#).
- Program [D18F2x250\\_dct\[0\]\[CmdTestEnable\]](#) = 0.

#### 2.9.8.1.1 Activate and Precharge Command Generation

Prior to sending read or write commands, BIOS must send an activate command to a row in a particular bank of the DRAM devices for access. To send an activate command, BIOS performs the following steps:

- Program [D18F2x28C\\_dct\[0\]](#) to the desired address as follows:
  - [CmdChipSelect](#) = CS[7:0].
  - [CmdBank](#) = BA[2:0].
  - [CmdAddress](#) = A[17:0] (row address).
- Program [D18F2x28C\\_dct\[0\]\[SendActCmd\]](#) = 1.
- Wait until [D18F2x28C\\_dct\[0\]\[SendActCmd\]](#) = 0.
- Wait 75 MEMCLKs. ([D18F2x200\\_dct\[0\]\\_mp\[1:0\]\[Tras, Trcd\]](#), [D18F2x204\\_dct\[0\]\\_mp\[1:0\]\[FourActWindow, Trrd, Trc\]](#))

After completing its accesses, BIOS must deactivate open rows in the DRAM devices. To send a precharge or precharge all command to deactivate open rows in a bank or in all banks, BIOS performs the following steps:

- Wait 25 MEMCLKs. ([D18F2x204\\_dct\[0\]\\_mp\[1:0\]\[Trtp\]](#))
- Program [D18F2x28C\\_dct\[0\]](#) to the desired address as follows:
  - [CmdChipSelect](#) = CS[7:0].
  - Precharge all command:
    - [CmdAddress\[10\]](#) = 1.
  - Precharge command:
    - [CmdAddress\[10\]](#) = 0.
    - [CmdBank](#) = BA[2:0].

- Program `D18F2x28C_dct[0][SendPchgCmd]` = 1.
- Wait until `D18F2x28C_dct[0][SendPchgCmd]` = 0.
- Wait 25 MEMCLKs. (Trp)

### 2.9.8.1.2 Read and Write Command Generation

BIOS performs the following steps for read pattern generation:

- Program `D18F2x27C_dct[0]`, `D18F2x278_dct[0]`, and `D18F2x274_dct[0]` with the data comparison masks for bit lanes of interest.
- Program `D18F2x270_dct[0][DataPrbsSeed]` the seed for the desired PRBS.
- Program `D18F2x260_dct[0][CmdCount]` equal to the number of cache line commands.
- Program `D18F2x25C_dct[0][BubbleCnt, CmdStreamLen]`. See 2.9.8.1.5 [BubbleCnt and CmdStream-Len Programming].
- Program `D18F2x25[8,4]_dct[0]` to the initial address (column address).
- Program `D18F2x250_dct[0]` as follows:
  - ResetAllErr and StopOnErr as desired. See 2.9.8.1.4 [Data Comparison].
  - CmdTgt corresponding to `D18F2x25[8,4]_dct[0]`.
  - CmdType = 000b.
  - SendCmd = 1.
- If `D18F2x260_dct[0][CmdCount] != 0` (not in infinite mode) then
  - Wait for `D18F2x250_dct[0][TestStatus] = 1` and `D18F2x250_dct[0][CmdSendInProg] = 0`.
  - Else
    - Wait the desired amount of time.
    - Program `D18F2x260_dct[0][CmdCount] = 1`.
    - Wait for `D18F2x250_dct[0][TestStatus] = 1` and `D18F2x250_dct[0][CmdSendInProg] = 0`.
- Program `D18F2x250_dct[0][SendCmd] = 0`.
- Read `D18F2x264_dct[0]`, `D18F2x268_dct[0]`, and `D18F2x26C_dct[0]` if applicable.

BIOS performs the following steps for write pattern generation:

- Program `D18F2x270_dct[0][DataPrbsSeed]` the seed for the desired PRBS.
- Program `D18F2x260_dct[0][CmdCount]` equal to the number of cache line commands desired.
- Program `D18F2x25C_dct[0][BubbleCnt, CmdStreamLen]`. See 2.9.8.1.5 [BubbleCnt and CmdStream-Len Programming].
- Program `D18F2x25[8,4]_dct[0]` to the initial address.
- Program `D18F2x250_dct[0]` as follows:
  - CmdTgt corresponding to `D18F2x25[8,4]_dct[0]`.
  - CmdType = 001b.
  - SendCmd = 1.
- If `D18F2x260_dct[0][CmdCount] != 0` (not in infinite mode) then
  - Wait for `D18F2x250_dct[0][TestStatus] = 1` and `D18F2x250_dct[0][CmdSendInProg] = 0`.
  - Else
    - Wait the desired amount of time.
    - Program `D18F2x260_dct[0][CmdCount] = 1`.
    - Wait for `D18F2x250_dct[0][TestStatus] = 1` and `D18F2x250_dct[0][CmdSendInProg] = 0`.
- Program `D18F2x250_dct[0][SendCmd] = 0`.

BIOS combines the two sets of steps listed above for alternating write and read pattern generation.

### 2.9.8.1.3 Configurable Data Patterns

In addition to PRBS mode, [D18F2x250\\_dct\[0\]\[DataPatGenSel\]](#) and [D18F2x2\[B4,B0,AC,A8\]\\_dct\[0\]](#) allow configurable data pattern generation. E.g. Simultaneous Switching Output (SSO) and Inversion Patterns.

**Table 53. Configurable Data Pattern Example with 1 Address Target**

| 1. D18F2x250_dct[0][DataPatGenSel] = 11b //User data pattern with circular lane shift<br>D18F2x2[B4,B0,AC,A8]_dct[0] = {FFEE_DDCCh, BBAA_9988h, 7766_5544h, 3322_1100h} |                  |           |           |           |           |           |           |                  |           |           |            |            |            |            |            |                  |            |            |            |            |            |            |            |            |     |

**2.9.8.1.3.1 Static Data Pattern Override**

Software is also able to use the bits of [D18F2x280\\_dct\[0\]](#), [D18F2x284\\_dct\[0\]](#), and [D18F2x288\\_dct\[0\]](#) to override the DCT pattern generator on a DQ basis. This can only be used in the [D18F2x250\\_dct\[0\]\[DataPatGenSel\]](#) = 10b mode. Software programs the following to enable the mode:

- Program [D18F2x288\\_dct\[0\]\[PatOvrVal\]](#) to the data value desired.
- Program [D18F2x280\\_dct\[0\]\[DQPatOvrEn\[31:0\]\]](#), [D18F2x284\\_dct\[0\]\[DQPatOvrEn\[63:32\]\]](#), and [D18F2x288\\_dct\[0\]\[EccPatOvrEn\]](#) to enable the override on the desired bit lanes.

**Table 55. Data Pattern Override Example with 1 Address Target**

| ECC7                                                                                                                                                                                                                                                                                                                                                                                                        | 1                | 1         | 1         | 0         | 1         | 1         | 1         | 1                | 1         | 1         | 0          | 1          | 1          | 1          | 1          | 1                | 1          | 1          | 1          | 0          | 1          | 1          | 1          | 1          | 1  |   |
| 1. D18F2x250_dct[0][DataPatGenSel] = 10b //Configurable data pattern<br>D18F2x2[B4,B0,AC,A8]_dct[0] = {FFEE_DDCCh, BBAA_9988h, 7766_5544h, 3322_1100h}<br>D18F2x288_dct[0][PatOvrVal] = 0. //Static 0's<br>D18F2x280_dct[0][DQPatOvrEn[31:0]] = 0x0000_0080. // DQ7 Override<br>D18F2x284_dct[0][DQPatOvrEn[63:32]] = 0x0000_0000. // No Override<br>D18F2x288_dct[0][EccPatOvrEn] = 0x10. // ECC4 Override |                  |           |           |           |           |           |           |                  |           |           |            |            |            |            |            |                  |            |            |            |            |            |            |            |            |    |   |

**2.9.8.1.3.2 Xor Data Pattern Override**

Software is also able to use the bits of D18F2x288\_dct[0][XorPatOvr] to override the DCT pattern generator with the same XOR function for all byte lanes. This feature can only be used with select

D18F2x250\_dct[0][DataPatGenSel] PRBS modes. Software programs the following to enable the mode:

- Program [D18F2x288\\_dct\[0\]\[XorPatOvr\]](#) to the data value of the XOR function desired.
  - Output data = IF (DQPatOvrEn) THEN PatOvrVal ELSE (DataPatGen ^ XorPatOvr) ENDIF.

#### 2.9.8.1.4 Data Comparison

The DCT compares the incoming read data against the expected pattern sequence during pattern generation. BIOS may choose to continue command generation and accumulate errors or stop command generation on the first error occurrence by programming [D18F2x250\\_dct\[0\]\[StopOnErr\]](#).

Error information is reported via [D18F2x264\\_dct\[0\]](#), [D18F2x268\\_dct\[0\]](#), [D18F2x26C\\_dct\[0\]](#), [D18F2x294\\_dct\[0\]](#), [D18F2x298\\_dct\[0\]](#) and [D18F2x29C\\_dct\[0\]](#). Error information can be masked on per-bit basis by programming [D18F2x274\\_dct\[0\]](#), [D18F2x278\\_dct\[0\]](#), and [D18F2x27C\\_dct\[0\]](#).

BIOS resets the error information by programming [D18F2x250\\_dct\[0\]\[ResetAllErr\]](#)=1.

Error information is only valid in certain modes of [D18F2x250\\_dct\[0\]\[CmdType\]](#), [D18F2x250\\_dct\[0\]\[CmdTgt\]](#) and [D18F2x260\\_dct\[0\]\[CmdCount\]](#) and when using 64 byte aligned addresses in [D18F2x25\[8,4\]\\_dct\[0\]\[TgtAddress\]](#). Some modes require a series of writes to setup a DRAM data pattern. See [Table 56](#).

**Table 56. Command Generation and Data Comparison**

| Commands   | CmdType | Cmd Tgt          | Maximum CmdCount <sup>4</sup> |
|------------|---------|------------------|-------------------------------|
| Read       | 000b    | 00b <sup>1</sup> | 128                           |
|            |         | 01b <sup>1</sup> | 256 <sup>2</sup>              |
| Write-Read | 010b    | 00b              | Infinite                      |
|            |         | 01b <sup>3</sup> | 256 <sup>2</sup>              |

1. Requires setup writes to store a data pattern in DRAM. The write commands are generated using the same CmdTgt, CmdCount, and DataPrbsSeed settings.
2. D18F2x254[TgtAddress] != D18F2x258[TgtAddress].
3. Requires setup writes to store a data pattern in DRAM. The write commands are generated programming D18F2x254[TgtAddress] to the intended Target B, CmdTgt=00b, CmdCount to 1/2 of the intended command count, and the same DataPrbsSeed setting.
4. D18F2x250\_dct[0][LsfrRollOver]=0. The maximum CmdCount is infinite for all modes listed if D18F2x250\_dct[0][LsfrRollOver]=1.

##### 2.9.8.1.4.1 Activate and Precharge Traffic Generation

The DCT generates ACT and PRE traffic in the available command bandwidth during a WR or RD sequence generated by [D18F2x250\\_dct\[0\]\[SendCmd\]](#) when [D18F2x250\\_dct\[0\]\[ActPchgGenEn\]](#)=1. This 16 command sequence repeats until the WR or RD initiated by SendCmd hits a stopping condition.

Software is able to adjust the command spacing and address sequence by programming [D18F2x28C\\_dct\[0\]\[CmdChipSelect\]](#), [D18F2x28C\\_dct\[0\]\[CmdAddress\[17:4\]\]](#), [D18F2x2B8\\_dct\[0\]\[ActPchgSeq\]](#), [D18F2x2B8\\_dct\[0\]\[ActPchgCmdMin\]](#), and [D18F2x2\[0,BC\]\\_dct\[0\]](#).

The banks specified by [D18F2x2\[C0,BC\]\\_dct\[0\]](#) must be in the idle state and must not conflict with the banks used by the SendCmd WR or RD traffic stream. Software is responsible for the ACT/PRE protocol of the WR or RD targets initiated by SendCmd. On a stopping condition for the WR or RD traffic stream, software is responsible for returning all of the possibly open banks to the idle state.

- Example configuration for DRAM Training:
- [D18F2x250\\_dct\[0\]](#)[ActPchgGenEn, CmdTgt, CmdType] = { 1b, 1b, 0b}. // Tgt A&B, Reads
- [D18F2x28C\\_dct\[0\]](#)[CmdChipSelect] = CS of TgtA
- [D18F2x28C\\_dct\[0\]](#)[CmdAddress[17:4]] = desired upper row address bits.
  - Hardware places the sequence number in row address [3:0].
- [D18F2x2B8\\_dct\[0\]](#)[ActPchgSeq, ActPchgCmdMin] = { 0F0Fh, Fh}.
- [D18F2x2BC\\_dct\[0\]](#) = 5432\_ 5432h; // Banks 2,3,4,5
- [D18F2x2C0\\_dct\[0\]](#) = 7632\_ 7632h; // Banks 2,3,6,7

#### 2.9.8.1.5 BubbleCnt and CmdStreamLen Programming

BIOS programs [D18F2x25C\\_dct\[0\]](#)[BubbleCnt2, BubbleCnt, CmdStreamLen] to ensure proper channel command spacing in command generation mode.

For continuous pattern generation it is expected that BubbleCnt = 0. In other modes, BIOS programs BubbleCnt, BubbleCnt2, and CmdStreamLen greater than or equal to the relevant DRAM timing parameters shown below to prevent contention on the DRAM bus. In all cases, if the minimum BubbleCnt > 0 or CmdType = 010b then BIOS programs CmdStreamLen = 1.

**Table 57. DDR3 Command Generation and BubbleCnt Programming**

| Commands                 | CmdType | CmdTgt | BubbleCnt                                                                                                                                | BubbleCnt2                                            |

### 2.9.9 Memory Interleaving Modes

The processor supports the following memory interleaving modes:

- Chip select: interleaves the physical address space over multiple DIMM ranks on a channel, as opposed to each DIMM owning single consecutive address spaces. See 2.9.9.1 [Chip Select Interleaving].

**Table 58. Recommended Interleave Configurations**

| Interleaving Mode        | Enabled                                                            | Disabled                    |
|--------------------------|--------------------------------------------------------------------|-----------------------------|
| Chip Select Interleaving | Number of chip selects installed on the channel is a power of two. | Requirements not satisfied. |

#### 2.9.9.1 Chip Select Interleaving

The chip select memory interleaving mode has the following requirements:

- The number of chip selects interleaved is a power of two.
- The chip selects are the same size and type.

A BIOS algorithm for programming D18F2x[5C:40]\_dct[0] [DRAM CS Base Address] and D18F2x[6C:60]\_dct[0] [DRAM CS Mask] in memory interleaving mode is as follows:

1. Program all DRAM CS Base Address and DRAM CS Mask registers using contiguous normalized address mapping.
2. For each enabled chip select, swap the corresponding BaseAddr[38:27] bits with the BaseAddr[21:11] bits as defined in Table 59.
3. For each enabled chip select, swap the corresponding AddrMask[38:27] bits with the AddrMask[21:11] bits as defined in Table 59.

**Table 59. DDR3 Swapped Normalized Address Lines for CS Interleaving**

| Condition                                                                                          |         |                       |                             | Swapped Base Address and Address Mask bits |                       |
|----------------------------------------------------------------------------------------------------|---------|-----------------------|-----------------------------|--------------------------------------------|-----------------------|
| DIMM Address Map <sup>1</sup>                                                                      | CS Size | BankSwap <sup>2</sup> | DctSelBankSwap <sup>2</sup> | 4 way CS interleaving                      | 2 way CS interleaving |
| 0001b                                                                                              | 256MB   | 0                     | -                           | [29:28] and [17:16]                        | [28] and [16]         |

### 2.9.10 Memory Hoisting

Memory hoisting reclaims the otherwise inaccessible DRAM that would naturally reside in memory regions used by MMIO. When memory hoisting is configured by BIOS, DRAM physical addresses are repositioned above the 4 GB address level in the address map. In operation, the physical addresses are remapped in hardware to the normalized addresses used by a DCT.

The region of DRAM that is hoisted is defined to be from [D18F1xF0](#)[DramHoleBase] to the 4 GB level. Hoisting is enabled by programming [D18F1xF0](#) [DRAM Hole Address] and configuring the DCTs per the equations in this section.

DramHoleSize is defined in order to simplify the following equations in this section and is calculated as follows:

- Define the DRAM hole region as  $\text{DramHoleSize}[31:24] = 100\text{h} - \text{D18F1xF0}[\text{DramHoleBase}[31:24]]$ .

### 2.9.10.1 DramHoleOffset Programming

$\text{D18F1xF0}[\text{DramHoleOffset}]$  is programmed to account for the addresses from  $\text{D18F1xF0}[\text{DramHoleBase}]$  to 4 GB when it falls inside of a  $\text{D18F1x2}[1,0][8,0][\text{DctBaseAddr}]$  and  $\text{D18F1x2}[1,0][\text{C},4][\text{DctLimitAddr}]$  region. See Figure 4 as an example memory population.

- Program  $\text{D18F1xF0}[\text{DramHoleOffset}[31:23]] = \{\text{DramHoleSize}[31:24], 0\text{b}\} + \{\text{DctBaseAddr}[31:27], 0000\text{b}\};$

**Figure 4: Memory Configuration with Memory Hole inside of Region**

$\text{D18F1xF0}[\text{DramHoleOffset}]$  is unused when the memory hole falls outside of a region. Figure 5 shows an example memory population which uses two memory regions. Region 1 is configured to begin above the memory hole.

**Figure 5: Memory Configuration with Memory Hole outside of Region**

### 2.9.11 DRAM CC6/PC6 Storage

DRAM is used to hold the state information of cores entering the CC6 power management state. As part of the system setup if CC6 or PC6 is enabled, BIOS configures a special region of DRAM to hold the state information. In operation, hardware protects this region from general system accesses while allowing the cores access during C-state transitions.

#### 2.9.11.1 Fixed Storage

The size of each special DRAM storage region is defined to be a fixed 16MB. BIOS configures the storage region at the top of the DRAM range, adjusts [D18F1x\[7:4\]\[C,4\]\[DramLimit\]](#) and the processor top of DRAM specified by [MSRC001\\_001A\[TOM\]](#) or [MSRC001\\_001D\[TOM2\]](#) downward accordingly. For UNB designs, the 16MB range is implemented in HW by adjusting [D18F1x124\[DramLimitAddr\]](#). See [Table 60](#).

After finalizing the system DRAM configuration, BIOS must set [D18F2x118\[LockDramCfg\] = 1](#) to enable the hardware protection.

**Table 60. Example storage region configuration**

| Node | DRAM Populated | D18F1x[17C:140,7C:40]<br>[DramBase, DramLimit] | CC6<br>DRAM<br>Range  | D18F4x128<br>[CoreStateSa<br>veDestNode] | D18F1x120[DramBaseAddr],<br>D18F1x124[DramLimitAddr] |
|------|----------------|------------------------------------------------|-----------------------|------------------------------------------|------------------------------------------------------|
| 0    | 256 MB         | 0 MB,<br>240 MB - 1                            | 240 MB,<br>256 MB - 1 | 0                                        | 0 MB,<br>256 MB - 1                                  |

### 2.9.12 DRAM On DIMM Thermal Management and Power Capping

Each DCT can throttle commands based on the state of the channel EVENT\_L pin or when D18F2xA4[BwCapEn]=1. The EVENT\_L pin is used for thermal management while D18F2xA4[BwCapEn] limits memory power independent of the thermal management solution.

The recommended BIOS configuration for the EVENT\_L pin is as follows:

- BIOS may enable command throttling on a DRAM controller if the platform supports the EVENT\_L pin by programming D18F2xA4[ODTSEn] = 1.
  - The recommended usage is for this pin to be connected to one or more JEDEC defined on DIMM temperature sensors. The DIMM SPD ROM indicates on DIMM temperature sensor support.
  - BIOS configures the temperature sensor(s) to assert EVENT\_L pin active low when the trip point is exceeded and deassert EVENT\_L when the temperature drops below the trip point minus the sensor defined hysteresis.
  - BIOS programs D18F2xA4[CmdThrottleMode] with the throttling mode to employ when the trip point has been exceeded.
  - The hardware enforces a refresh rate of 3.9 us while EVENT\_L is asserted.
- BIOS configures D18F2x8C\_dct[0][Tref] based on JEDEC defined temperature range options, as indicated by the DIMM SPD ROM. The two defined temperature ranges are normal (with a case temperature of 85 °C) and extended (with a case temperature of 95 °C). The following recommendation assumes JEDEC defined SPD Byte 31[Extended Temperature Refresh Rate] = 1 devices will not be available in the near future.
  - If all DIMMs support the normal temperature range, or if normal and extended temperature range DIMMs are mixed, BIOS programs D18F2x8C\_dct[0][Tref] to 7.8 us and D18F2xA4[ODTSEn] = 1, or D18F2x8C\_dct[0][Tref] to 3.9 us. BIOS configures the temperature sensor trip point for all DIMMs according to the 85 °C case temperature specification.
  - If all DIMMs support the extended temperature range, BIOS has two options:
    - a. Follow the recommendation for normal temperature range DIMMs.
    - b. Program D18F2x8C\_dct[0][Tref] = 3.9 us and configure the temperature sensor trip point for all DIMMs according to the 95 °C case temperature specification.
- At startup, the BIOS determines if the DRAMs are hot before enabling a DCT and delays for an amount of time to allow the devices to cool under the influence of the thermal solution. This is accomplished by checking the temperature status in the temperature sensor of each DIMM.
- The DCT latched status of the EVENT\_L pin for can be read by system software in D18F2xAC [DRAM Controller Temperature Status].

The relationship between the DRAM case temperature, trip point, and EVENT\_L pin sampling interval is outlined as follows:

- The trip point for each DIMM is ordinarily configured to the case temperature specification minus a guardband temperature for the DIMM.
- The temperature guardband is vendor defined and is used to account for sensor inaccuracy, EVENT\_L pin sample interval, and platform thermal design.

- The sampling interval is vendor defined. It is expected to be approximately 1 second.

BIOS may enable bandwidth capping on a DRAM controller by setting [D18F2xA4](#)[BwCapEn] = 1 and programming [D18F2xA4](#)[BwCapCmdThrottleMode] with the throttling mode to employ. The DCT will employ the larger of the two throttling percentages as specified by [D18F2xA4](#)[BwCapCmdThrottleMode] and [D18F2xA4](#)[CmdThrottleMode] if the EVENT\_L pin is asserted when both [D18F2xA4](#)[BwCapEn] = 1 and [D18F2xA4](#)[ODTSEn] = 1.

## 2.10 Thermal Functions

Thermal functions SB-TSI, HTC, PROCHOT\_L and THERMTRIP are intended to maintain processor temperature in a valid range by:

- Providing a signal to external circuitry for system thermal management like fan control.
- Lowering power consumption by switching to lower-performance P-state.
- Sending processor to the THERMTRIP state to prevent it from damage.

The processor thermal-related circuitry includes (1) the temperature calculation circuit (TCC) for determining the temperature of the processor and (2) logic that uses the temperature from the TCC. The processor includes a thermal diode as an alternative method for temperature measurement when used with an external thermal diode monitor. The thermal diode does not directly interact with the thermal functions.

### 2.10.1 The Tctl Temperature Scale

Tctl is a processor temperature control value used for processor thermal management. Tctl is accessible through SB-TSI and [D18F3xA4](#)[CurTmp]. Tctl is a temperature on its own scale aligned to the processors cooling requirements. Therefore Tctl does not represent a temperature which could be measured on the die or the case of the processor. Instead, it specifies the processor temperature relative to the maximum operating temperature, Tctl,max. Tctl,max is specified in the power and thermal data sheet. Tctl,max is 70 C for lidded processors and 100 C for lidless processors. Tctl is defined as follows for all parts:

A: For  $Tctl = Tctl\_max$  to 255.875: the temperature of the part is  $[Tctl - Tctl\_max]$  over the maximum operating temperature. The processor may take corrective actions that affect performance, such as HTC, to support the return to Tctl range B.

B: For  $Tctl = 0$  to  $Tctl\_max - 0.125$ : the temperature of the part is  $[Tctl\_max - Tctl]$  under the maximum operating temperature.

**Figure 6: Tctl scale**

### 2.10.2 Temperature Slew Rate Control

The temperature slew rate controls in [D18F3xA4](#) are used to filter processor the processor temperature provided in [D18F3xA4](#)[CurTmp] and through SB-TSI. Separate controls are provided for increasing and decreasing temperatures. The latest measured temperature is referred to as Tctlm below.

If downward slew control is enabled ([D18F3xA4](#)[TmpSlewDnEn]), Tctl is not updated down unless Tctlm remains below Tctl for a time specified by [D18F3xA4](#)[PerStepTimeDn]. If at any point before the timer expires Tctlm equals or exceeds Tctl, then the timer resets and Tctl is not updated. If the timer expires, then Tctl is reduced by 0.125. If downward slew control is disabled, then if Tctlm is less than Tctl, Tctl is immediately updated to Tctlm.

The upward slew control works similar to downward slew control except that if Tctlm exceeds Tctl by a value defined by [D18F3xA4](#)[TmpMaxDiffUp] then Tctl is immediately updated to Tctlm. Otherwise, Tctlm must remain above Tctl for time specified by [D18F3xA4](#)[PerStepTimeUp] before Tctl is incremented by 0.125.

### 2.10.3 Temperature-Driven Logic

The temperature calculated by the TCC is used by SB-TSI, HTC, THERMTRIP, and PROCHOT\_L.

#### 2.10.3.1 PROCHOT\_L and Hardware Thermal Control (HTC)

The processor *HTC-active state* is characterized by (1) the assertion of PROCHOT\_L, (2) reduced power consumption, and (3) reduced performance. While in the HTC-active state, the processor reduces power consumption by limiting all cores to a P-state (specified by [D18F3x64](#)[HtcPstateLimit]). See [2.5.3 \[CPU Power Management\]](#). While in the HTC-active state, software should not change the following: All [D18F3x64](#) fields

(except for HtcActSts and HtcEn), [MSRC001\\_001F](#)[DisProcHotPin]. Any change to the previous list of fields when in the HTC-active state can result in undefined behavior. HTC status and control is provided through [D18F3x64](#).

The PROCHOT\_L pin acts as both an input and as an open-drain output. As an output, PROCHOT\_L is driven low to indicate that the HTC-active state has been entered due to an internal condition, as described by the following text. The minimum assertion and deassertion time for PROCHOT\_L is 15 ns.

The processor enters the HTC-active state if all of the following conditions are true:

- [D18F3xE8](#)[HtcCapable]=1
- [D18F3x64](#)[HtcEn]=1
- PWROK=1
- THERMTRIP\_L=1
- The processor is not in the C3 ACPI state.

and any of the following conditions are true:

- Tctl is greater than or equal to the HTC temperature limit ([D18F3x64](#)[HtcTmpLmt]).
- PROCHOT\_L=0

The processor exits the HTC-active state when all of the following are true:

- Tctl is less than the HTC temperature limit ([D18F3x64](#)[HtcTmpLmt]).
- Tctl has become less than the HTC temperature limit ([D18F3x64](#)[HtcTmpLmt]) minus the HTC hysteresis limit ([D18F3x64](#)[HtcHystLmt]) since being greater than or equal to the HTC temperature limit ([D18F3x64](#)[HtcTmpLmt]).
- PROCHOT\_L=1.

The default value of the HTC temperature threshold (Tctl\_max) is specified in the Power and Thermal Data-sheet.

### 2.10.3.2 Local Hardware Thermal Control (LHTC)

The *LHTC-active state* of a core is characterized by (1) reduced power consumption and (2) reduced performance of the core. While in the LHTC-active state, the core reduces power consumption by limiting the maximum P-state specified by [D0F0xBC\\_x3FA1C](#)[LhtcActivePstateLimit]. See [2.5.3.1 \[Core P-states\]](#).

The LHTC trip point is the same for all cores and is specified by Fuse[LhtcTmpLmt]. The LHTC-active state is independent from the HTC-active state. LHTC does not affect PROCHOT\_L output and is not affected by PROCHOT\_L input.

A core enters the LHTC-active state if all of the following conditions are true:

- PWROK is asserted.
- The processor is not in the package C6 (PC6) state.
- Tctl maximum for all TCENs is greater than or equal to LHTC temperature limit (specified by Fuse[LhtcTmpLmt]).

A core exits the LHTC-active state when all of the following are true:

- Tctl maximum for all TCENs is less than LHTC temperature low limit (specified by Fuse[LhtcHystLmt]) since being greater than or equal to the LHTC temperature high limit (specified by Fuse[LhtcTmpLmt]).

### 2.10.3.3 Software P-state Limit Control

[D18F3x68](#) [Software P-state Limit] provides a software mechanism to limit the P-state [MSRC001\\_0061](#)[CurP-

stateLimit]. See [2.5.3 \[CPU Power Management\]](#).

#### 2.10.3.4 THERMTRIP

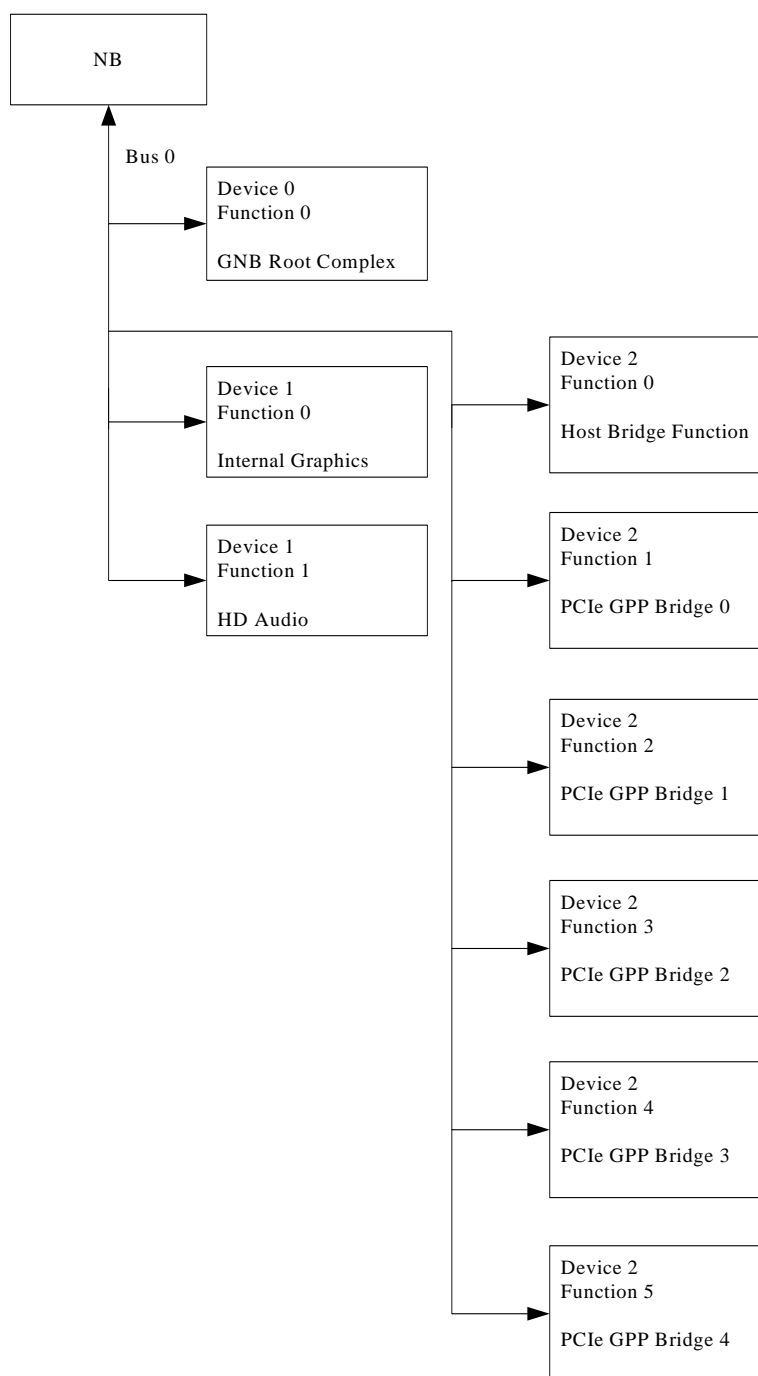

If the processor supports the THERMTRIP state (as specified by [D18F3xE4](#)[ThermtpEn] or [CUID Fn8000\\_0007\\_EDX](#)[TTP], which are the same) and the temperature approaches the point at which the processor may be damaged, the processor enters the THERMTRIP state. The THERMTRIP function is enabled after cold reset (after PWROK asserts and RESET\_L deasserts). It remains enabled in all other processor states, except during warm reset (while RESET\_L is asserted). The THERMTRIP state is characterized as follows:

- The THERMTRIP\_L signal is asserted.
- Nearly all clocks are gated off to reduce dynamic power.
- A low-value VID is generated. Specified by Fuse[ThermVid]; [MSRC001\\_0071](#)BOZOfieldNotFound[Min-Vid] is ignored for this voltage transition.
- In addition, the external chipset is expected to place the system into the S5 ACPI state (power off) if THERMTRIP\_L is detected to be asserted.

A cold reset is required to exit the THERMTRIP state.

## 2.11 Root Complex

### 2.11.1 Overview

**Figure 7: Root complex topology**

### 2.11.2 Interrupt Routing

The GNB includes a fully programmable IOAPIC. The IOAPIC registers are accessed through the [D0F0xF8](#) index and [D0F0xFC](#) data pair registers using two back-to-back config cycles. PCI defined INTx interrupts for

each bridge are routed to IOAPIC pins via the bridge interrupt routing registers located at [D0F0xFC\\_x1\[4:0\]](#).

### 2.11.2.1 IOAPIC Configuration

The IOAPIC configuration is performed by the following sequence:

1. Set the base address for the memory mapped registers by programming [D0F0xFC\\_x01](#)[IoapicAddr] and [D0F0xFC\\_x02](#)[IoapicAddrUpper].
2. Enable IOAPIC by programming [D0F0xFC\\_x00](#)[IoapicEnable] = 1.
3. Only if the system is in PIC mode, program [D0F0xFC\\_x00](#)[IoapicSbFeatureEn] = 1. This bit should be programmed to 0 when the system is in APIC mode.

The IOAPIC has a total of 29 interrupt inputs. These inputs are as follows:

- 5 groups of PCIe interrupts each having a 4-bit external interrupt bus (INT A/B/C/D) and a 1-bit bridge interrupt, and
- a 4-bit external interrupt bus from GBIF.

The recommended interrupt routing and swizzling configuration is as shown in [Table 61](#).

**Table 61: Recommended Interrupt Routing and Swizzling Configuration**

| Device  | Register                                     | Setting | Description                                                                        |

|         | <a href="#">D0F0xFC_x0F</a> [GBIFExtIntrSwz] | 0h      |                                                                                    |

### 2.11.3 Links

#### 2.11.3.1 Overview

There is one 5 x8 PCIe core with five configurable ports. These ports can be divided into 2 groups:

- Gfx: Contains 1 x4 port to create a 4-bit Gfx lane using the upper 4 lanes of the PCIe core.
- GPP: Contains upto 4 General Purpose Ports (GPP) using the lower 4 lanes of the PCIe core.

All PCIe links are capable of supporting Gen1/Gen2 data rates. Function 0 in Device 2 does not control any

hardware. It is always enabled and allows software to scan through all the functions of the device.

Gfx and GPP ports each have a Type 1 Virtual PCI-to-PCI bridge header in the PCI configuration space mapped to devices according to [Figure 7](#).

Each PCIe lane is assigned a unique lane ID that software uses to communicate configuration information to the SMU. [Table 88](#) shows the mapping between lane ID's and lanes.

### 2.11.3.2 Link Configurations

Lanes of the Gfx ports can be assigned to IO links.

- For each 1x lane, program [D0F0xE4\\_x0130\\_0\[C:8\]04\[StrapBifMaxPayloadSupport\]=1h](#). Max Payload Support = 256 for performance.

The following link configurations are supported for the GPP links:

**Table 62: Supported General Purpose (GPP) Link Configurations**

| D0F0xE4    |            | GPP Port Lane |         |         |         |         |
|------------|------------|---------------|---------|---------|---------|---------|
| x0130_0080 | x0110_0011 | Lanes[7:4]    | 3       | 2       | 1       | 0       |
| 0000_0001h | 0000_0300h | x4 Link (Gfx) | x4 Link |         |         |         |
| 0000_0002h | 0000_0203h | x4 Link (Gfx) | x2 Link |         | x2 Link |         |
| 0000_0003h | 0000_0201h | x4 Link (Gfx) | x1 Link | x1 Link | x2 Link |         |
| 0000_0004h | 0000_0200h | x4 Link (Gfx) | x1 Link | x1 Link | x1 Link | x1 Link |

### 2.11.4 Root Complex Configuration

#### 2.11.4.1 LPC MMIO Requirements

To ensure proper operation of LPC generated DMA requests, the FCH must be configured to send processor generated MMIO writes that target the LPC bus to the FCH as non-posted writes. The MMIO address space of the LPC bus must not be included in the ranges specified by [D18F1x\[2CC:2A0,1CC:180,BC:80\] \[MMIO Base/Limit\]](#) and non-posted protocol for memory writes must be enabled using the following programming before LPC DMA transactions are initiated.

- Program [D0F0x98\\_x06\[UmiNpMemWrEn\]](#) = 1.

#### 2.11.4.2 Configuration for non-FCH Bridges

BIOS should program the following in non-FCH bridges:

- Program [D0F0xCC\\_x01\[CrsEnable\]](#) = 1 for [D0F0xC8\[NbDevIndSel\]](#) = 11h-15h.
- Program [D0F0xCC\\_x01\[SetPowEn\]](#) = 1 for [D0F0xC8\[NbDevIndSel\]](#) = 11h-15h.

#### 2.11.4.3 Link Configuration and Initialization

Link configuration and initialization is performed by the following sequence:

- [2.11.4.3.1 \[Link Configuration and Core Initialization\]](#)
- [2.11.4.3.2 \[Link Training\]](#)
- [2.11.4.5 \[Link Power Management\]](#)
- Lock link configuration registers.

- Program D0F0xE4\_x0140\_0010[HwInitWrLock] = 1.
- Program D0F0x64\_x00[HwInitWrLock] = 1.

#### 2.11.4.3.1 Link Configuration and Core Initialization

Link configuration is done on a per link basis. Lane reversal, IO link selection, and lane enablement is configured through this sequence.

1. Place software-reset module into blocking mode:
  - A. Program D0F0xE4\_x0130\_8062[ConfigXferMode]=0.
  - B. Program D0F0xE4\_x0130\_8062[BlockOnIdle]=0.
2. If the link is an IO link, Program D0F0xE4\_x0140\_0011[DynClkLatency]=Fh.
3. Program D0F0xE4\_x0130\_0080 per Table 62.
4. Program D0F0xE4\_x0130\_802[4:1] per Table 62.
5. Program D0F0xE4\_x0110\_0010[RxDetectTxPwrMode]=1.
6. Program D0F0xE4\_x0110\_0010[LS2ExitTime]=000b.
7. Program D0F0xE4\_x0130\_8013[MasterPciePllA, MasterPciePllB] per Table 62.
8. Initiate core reconfiguration sequence:
  - A. Program D0F0xE4\_x0130\_8062[ReconfigureEn]=1.
  - B. Program D0F0xE4\_x0130\_8060[Reconfigure]=1.
  - C. Wait for D0F0xE4\_x0130\_8060[Reconfigure]==0.
  - D. Program D0F0xE4\_x0130\_8062[ReconfigureEn]=0.
9. Return software-reset module to non-blocking mode:
  - A. Program D0F0xE4\_x0130\_8062[ConfigXferMode]=1.
10. Program D2F[5:1]xE4\_xC1[StrapReverseLanes] if necessary.
11. Program D0F0xE4\_x0110\_0011 per Table 62.
12. For each nibble that has no PCIe lanes in use:
  - A. Program D0F0xE4\_x0110\_001[8:7,3:2][PllPowerStateInOff]=111b.
  - B. Program D0F0xE4\_x0110\_001[8:7,3:2][PllPowerStateInTxs2]=111b.
  - C. Program D0F0xE4\_x0110\_001[8:7,3:2][TxPowerStateInTxs2]=111b.
  - D. Program D0F0xE4\_x0110\_001[8:7,3:2][RxPowerStateInRxs2]=111b.
13. For each lane that is not in use, program the corresponding D0F0xE4\_x0130\_8029[LaneEnable]=0.
14. Configure PIF parings:
  - A. Program D0F0xE4\_x0110\_0011=0000\_0300h.

#### 2.11.4.3.2 Link Training

Link training is performed on a per link basis. BIOS may train the links in parallel.

#### 2.11.4.4 Miscellaneous Features

##### 2.11.4.4.1 Lane Reversal

Normally, the lanes of each port are physically numbered from n-1 to 0 where n is the number of lanes assigned to the port. Physical lane numbering can be reversed according to the following methods:

- To reverse the physical lane numbering for a specific port, program D2F[5:1]xE4\_xC1[StrapReverseLanes]=1.
- To reverse the physical lane numbering for all ports in the GPP or GFX interfaces, program D0F0xE4\_x0140\_00C0[StrapReverseAll]=1.

Note that logical port numbering is established during link training regardless of the physical lane numbering.

#### 2.11.4.4.2 Link Speed Changes

Link speed changes can only occur on Gen2 capable links. To verify that Gen2 speeds are supported verify `D2F[5:1]x64[LinkSpeed]==02h`.

##### 2.11.4.4.2.1 Autonomous Link Speed Changes

To enable autonomous speed changes on a per port basis:

1. Program `D2F[5:1]x88[TargetLinkSpeed]=2h`.
2. Program `D0F0xE4_x0130_0[C:8]03[StrapBifDeemphasisSel]=1`.
3. Program `D2F[5:1]xE4_xA4[LcGen2EnStrap]=1`.
4. Program `D2F[5:1]xE4_xC0[StrapAutoRcSpeedNegotiationDis]=0`.
5. Program `D2F[5:1]xE4_xA4[LcMultUpstreamAutoSpdChngEn]=1`.
6. Program `D2F[5:1]xE4_xA2[LcUpconfigureDis]=0`.

##### 2.11.4.4.3 Deemphasis

Deemphasis strength can be changed on a per-port basis by programming `D2F[5:1]xE4_xB5[LcSelectDeemphasis]`.

#### 2.11.4.5 Link Power Management

##### 2.11.4.5.1 Link States

To enable support for L1 program `D2F[5:1]xE4_xA0[LcL1Inactivity]=6h`.

To enable support for L0s:

- Program `D2F[5:1]xE4_xA1[LcDontGotoL0sifL1Armed]=1`.
- Program `D2F[5:1]xE4_xA0[LcL0sInactivity]=9h`.

##### 2.11.4.5.2 Dynamic Link-width Control

Dynamic link-width control is a power saving feature that reconfigures the link to run with fewer lanes. The inactive lanes are turned off to conserve power.

The Gfx link can switch among widths of: x1, x2, and x4, upto the maximum programmed port width.

The GPP link can switch among widths of: x1, x2, and x4, upto the maximum programmed port width.

The link width is controlled by the following 3 mechanisms:

- Up/Down Reconfiguration: The link is retrained according to the PCI Express specification. This mechanism is only available between Gen2 devices. .

The core has the capability to turn off the inactive lanes of trained links. To enable this feature program `D2F[5:1]xE4_xA2[LcDynLanesPwrState]=11b`.

#### 2.11.4.6 Link Test and Debug Features

##### 2.11.4.6.1 Compliance Mode

To enable Gen1 software compliance mode program `D2F[5:1]xE4_xC0[StrapForceCompliance]=1` for each port to be placed in compliance mode.

To enable Gen2 software compliance mode:

1. BIOS enables Gen2 capability by programming [D0F0xE4\\_x0140\\_00C1](#)[StrapGen2Compliance]=1.
2. Program [D2F\[5:1\]xE4\\_xA4](#)[LcGen2EnStrap]=1.
3. Program [D2F\[5:1\]x88](#)[TargetLinkSpeed]=2h for each port to be placed in compliance mode.
4. Program [D2F\[5:1\]x88](#)[EnterCompliance]=1 for each port to be placed in compliance mode.

### 2.11.5 BIOS Timer

The root complex implements a 32-bit microsecond timer (see [D0F0xE4\\_x0130\\_80F0](#) and [D0F0xE4\\_x0130\\_80F1](#)) that the BIOS can use to accurately time wait operations between initialization steps.

To ensure that BIOS waits a minimum number of microseconds between steps BIOS should always wait for one microsecond more than the required minimum wait time.

### 2.11.6 PCIe Client Interface Control

This interface is accessed through the indexed space registers located at [D0F2xF8](#) within the [Device 0 Function 2 Configuration Registers](#).

BIOS should perform the following steps to initialize the interface:

1. Program [D0F0x64\\_x0D](#)[PciDev0Fn2RegEn] = 1h.
2. Program credits for the BIF client as follows:
  - A. Program [D0F2xFC\\_x32\\_L1i\[1\]](#)[DmaNpHaltDis] = 1h.
  - B. Program [D0F2xFC\\_x32\\_L1i\[1\]](#)[DmaBufCredits] = 8h.
  - C. Program [D0F2xFC\\_x32\\_L1i\[1\]](#)[DmaBufMaxNpCred] = 8h.
3. Program credits for the PPD client as follows:
  - A. Program [D0F2xFC\\_x32\\_L1i\[0\]](#)[DmaBufCredits] = 8h.
  - B. Program [D0F2xFC\\_x32\\_L1i\[0\]](#)[DmaBufMaxNpCred] = 7h.
4. Program credits for the INTGEN client as follows:
  - A. Program [D0F2xFC\\_x32\\_L1i\[2\]](#)[DmaBufCredits] = 4h.
  - B. Program [D0F2xFC\\_x32\\_L1i\[2\]](#)[DmaBufMaxNpCred] = 4h.
5. Program clock gating as follows:
  - A. Program [D0F2xFC\\_x33](#)[L1DmaClkgateEn] = 1h.
  - B. Program [D0F2xFC\\_x33](#)[L1CacheClkgateEn] = 1h.
  - C. Program [D0F2xFC\\_x33](#)[L1CpslvClkgateEn] = 1h.
  - D. Program [D0F2xFC\\_x33](#)[L1DmaInputClkgateEn] = 1h.
  - E. Program [D0F2xFC\\_x33](#)[L1PerfClkgateEn] = 1h.
  - F. Program [D0F2xFC\\_x33](#)[L1MemoryClkgateEn] = 1h.
  - G. Program [D0F2xFC\\_x33](#)[L1RegClkgateEn] = 1h.
  - H. Program [D0F2xFC\\_x33](#)[L1HostreqClkgateEn] = 1h.
  - I. Program [D0F2xFC\\_x33](#)[L1L2ClkgateEn] = 1h.
6. Program [D0F0x64\\_x0D](#)[PciDev0Fn2RegEn] = 0h.

## 2.12 System Management Unit (SMU)

The system management unit (SMU) is a subcomponent of the northbridge that is responsible for a variety of system and power management tasks during boot and runtime. The SMU contains a Lattice LM32 microcontroller to assist with many of these tasks.

### 2.12.1 Software Interrupts

The microcontroller can be interrupted to cause it to perform several initialization and runtime tasks. BIOS and ACPI methods can interrupt the SMU to request a specific action using the following sequence:

1. If a service request requires an argument, program `D0F0xBC_xC210_003C`[Argument] with the desired argument.
1. Wait for `D0F0xBC_xC210_0004`[IntDone]==1.
2. Program `D0F0xBC_xC210_0000`[ServiceIndex] to the desired service index and toggle. This may be done in a single write.
3. Wait for `D0F0xBC_xC210_0004`[IntAck]==1.

After performing the steps above, software may continue execution before the interrupt has been serviced. However, software should not rely on the results of the interrupt until the service is complete (see `D0F0xBC_xC210_0004`[IntDone]). Interrupting the SMU with a service index that does not exist results in undefined behavior.

**Table 63: SMU Software Interrupts**

| Service Index | Notes                                                                                                                                                                                                                                                                                                                      |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1Eh           | Description: <b>BIOSMC_MSG_LCLK_DPM_ENABLE</b> . Enables LCLK DPM. See 2.5.6.1.3 [LCLK DPM].                                                                                                                                                                                                                               |
|               | Input: <code>D0F0xBC_x3FDC8</code>                                                                                                                                                                                                                                                                                         |
|               | Output: None.                                                                                                                                                                                                                                                                                                              |
| 3Ah           | Description: <b>BIOSMC_MSG_VDDNB_REQUEST</b> . Request VDDNB voltage.                                                                                                                                                                                                                                                      |
|               | Input: Program argument to desired voltage (encoded in mV with two fraction bits). Values outside <code>D18F5x17C</code> [MaxVid, MinVid] range are invalid and result in undefined behavior. <ul style="list-style-type: none"> <li>• <code>D0F0xBC_xC210_003C</code>[Argument] = (Desired Voltage in mV) * 4.</li> </ul> |
|               | Output: None.                                                                                                                                                                                                                                                                                                              |
| 43h           | Description: <b>BIOSMC_MSG_NBDPM_Enable</b> . Enables NB P-state Adjustments.                                                                                                                                                                                                                                              |
|               | Input: <code>D0F0xBC_x3F9E8</code>                                                                                                                                                                                                                                                                                         |
|               | Output: <code>D0F0xBC_x3F9EC</code>                                                                                                                                                                                                                                                                                        |

## 2.13 Graphics Processor (GPU)

The APU contains an integrated DX11 compliant graphics processor.

### 2.13.1 Graphics Memory Controller (GMC)

The graphics memory controller is responsible for servicing memory requests from the different blocks within the GPU and forwarding routing them to the appropriate interface. The GMC is also responsible for translating

GPU virtual address to GPU physical addresses and for translating GPU physical addresses to system addresses.

### 2.13.2 Frame Buffer (FB)

The frame buffer is defined as the portion of system memory dedicated for GPU use.

**Table 64: Recommended Frame Buffer Configurations**

| System Memory Size | Frame Buffer Size |
|--------------------|-------------------|
| < 1GB              | 64 MB             |
| >= 1GB & < 2GB     | 256 MB            |
| >= 2GB             | 512 MB            |

## 2.14 RAS Features

### 2.14.1 Machine Check Architecture

The processor contains logic and registers to detect, log, and correct errors in the data or control paths in each core and the Northbridge. The Machine Check Architecture (MCA) defines the facilities by which processor and system hardware errors are logged and reported to system software. This allows system software to perform a strategic role in recovery from and diagnosis of hardware errors.

Refer to the AMD64 Architecture Programmer's Manual for an architectural overview and methods for determining the processor's level of MCA support. See [1.2 \[Reference Documents\]](#).

The ability of hardware to generate a machine check exception upon an error is indicated by [CPUID Fn0000\\_0001\\_EDX\[MCE\]](#) or [CPUID Fn8000\\_0001\\_EDX\[MCE\]](#).

#### 2.14.1.1 Machine Check Registers

[CPUID Fn0000\\_0001\\_EDX\[MCA\]](#) or [CPUID Fn8000\\_0001\\_EDX\[MCA\]](#) indicates the presence of the following machine check registers:

- [MSR0000\\_0179 \[Global Machine Check Capabilities \(MCG\\_CAP\)\]](#)
  - Reports how many machine check register banks are supported.
- [MSR0000\\_017A \[Global Machine Check Status \(MCG\\_STAT\)\]](#)
  - Provides basic information about processor state after the occurrence of a machine check error.
- [MSR0000\\_017B \[Global Machine Check Exception Reporting Control \(MCG\\_CTL\)\]](#)
  - Used by software to enable or disable the logging and reporting of machine check errors in the error-reporting banks.

The error-reporting machine check register banks supported in this processor are:

- MC0: Data cache (DC).
- MC1: Instruction cache (IC).
- MC2: Bus unit (BU), including L2 cache.
- MC3: Reserved.
- MC4: Northbridge (NB), including the IO link. These MSRs are also accessible from configuration space. There is only one NB error-reporting bank, independent of the number of cores.
- MC5: Fixed-issue reorder buffer (FR) machine check registers.
- The register types within each bank are:
  - MCI\_CTL, Machine Check Control: Enables error reporting via machine check exception. The MCI\_CTL register in each bank must be enabled by the corresponding enable bit in MCG\_CTL ([MSR0000\\_017B](#)).
  - MCI\_STATUS, Machine Check Status: Logs information associated with errors.
  - MCI\_ADDR, Machine Check Address: Logs address information associated with errors.
  - MCI\_MISC, Machine Check Miscellaneous: Log miscellaneous information associated with errors, as defined by each error type.
  - MCI\_CTL\_MASK, Machine Check Control Mask: Inhibit detection of an error source unless otherwise specified.

The following table identifies the registers associated with each error-reporting machine check register bank:

**Table 65: MCA register cross-reference table**

| Register Bank (MCi) | MCA Register                 |                              |                              |                              |                              |
|---------------------|------------------------------|------------------------------|------------------------------|------------------------------|------------------------------|
|                     | CTL                          | STATUS                       | ADDR                         | MISC                         | CTL_MASK                     |
| MC0                 | <a href="#">MSR0000_0400</a> | <a href="#">MSR0000_0401</a> | <a href="#">MSR0000_0402</a> | <a href="#">MSR0000_0403</a> | <a href="#">MSRC001_0044</a> |
| MC1                 | <a href="#">MSR0000_0404</a> | <a href="#">MSR0000_0405</a> | <a href="#">MSR0000_0406</a> | <a href="#">MSR0000_0407</a> | <a href="#">MSRC001_0045</a> |
| MC2                 | <a href="#">MSR0000_0408</a> | <a href="#">MSR0000_0409</a> | <a href="#">MSR0000_040A</a> | <a href="#">MSR0000_040B</a> | <a href="#">MSRC001_0046</a> |
| MC3                 | <a href="#">MSR0000_040C</a> | <a href="#">MSR0000_040D</a> | <a href="#">MSR0000_040E</a> | <a href="#">MSR0000_040F</a> | <a href="#">MSRC001_0047</a> |
| MC4                 | <a href="#">MSR0000_0410</a> | <a href="#">MSR0000_0411</a> | <a href="#">MSR0000_0412</a> | <a href="#">MSR0000_0413</a> | <a href="#">MSRC001_0048</a> |
| MC5                 | <a href="#">MSR0000_0414</a> | <a href="#">MSR0000_0415</a> | <a href="#">MSR0000_0416</a> | <a href="#">MSR0000_0417</a> | <a href="#">MSRC001_0049</a> |

Corrected, deferred, and uncorrected errors are logged in MCi\_STATUS and MCi\_ADDR as they occur. Uncorrected errors that are enabled in MCi\_CTL result in a Machine Check exception.

Each MCi\_CTL register must be enabled by the corresponding enable bit in [MSR0000\\_017B \[Global Machine Check Exception Reporting Control \(MCG\\_CTL\)\]](#).

MCi\_CTL\_MASK allow BIOS to mask the presence of any error source from software for test and debug. When error sources are masked, it is as if the error was not detected. Such masking consequently prevents error responses and actions.

Each MCA bank implements a number of machine check miscellaneous registers, denoted as MCi\_MISCj, where j goes from 0 to a maximum of 8. If there is more than one MCi\_MISC register in a given bank, a non-zero value in MCi\_MISC0[BlkPtr] points to the contiguous block of additional registers.

The presence of valid information in the first MISC register in the bank (MCi\_MISC0) is indicated by MCi\_STATUS[MiscV]. The presence of valid information in additional implemented MISC registers is indicated by MCi\_MISCj[Val] in the target register.

#### 2.14.1.2 Machine Check Errors

The classes of machine check errors are, in priority order from highest to lowest:

- Uncorrected
- Deferred
- Corrected

Uncorrected errors cannot be corrected by hardware and may cause loss of data, corruption of processor state, or both. Uncorrected errors update the status and address registers if not masked from logging in MCi\_CTL\_MASK. Information in the status and address registers from a previously logged lower priority error is overwritten. Previously logged errors of the same priority are not overwritten. Uncorrected errors that are enabled in MCi\_CTL result in reporting to software via machine check exceptions. If an uncorrected error is masked from logging, the error is ignored by hardware (exceptions are noted in the register definitions). If an uncorrected error is disabled from reporting, containment of the error and logging/reporting of subsequent errors may be affected. Therefore, enable reporting of unmasked uncorrected errors for normal operation. Disable reporting of uncorrected errors only for debug purposes.

Deferred errors are errors that cannot be corrected by hardware, but do not cause an immediate interruption in

program flow, loss of data integrity, or corruption of processor state. These errors indicate that data has been corrupted but not consumed; no exception is generated because the data has not been referenced by a core or an IO link. Hardware writes information to the status and address registers in the corresponding bank that identifies the source of the error if deferred errors are enabled for logging. If there is information in the status and address registers from a previously logged lower priority error, it is overwritten. Previously logged errors of the same or higher priority are not overwritten. Deferred errors are not reported via machine check exceptions; they can be seen by polling the MCi\_STATUS registers.

Corrected errors are those which have been corrected by hardware and cause no loss of data or corruption of processor state. Hardware writes the status and address registers in the corresponding register bank with information that identifies the source of the error if they are enabled for logging. Corrected errors are not reported via machine check exceptions. Some corrected errors may be reported to software via error thresholding (see [2.14.1.7 \[Error Thresholding\]](#)).

The implications of these categories of errors are:

1. Uncorrected error; hardware did not deal with the problem.
  - Operationally (error handling), action required, because program flow is affected.
  - Diagnostically (fault management), software may collect information to determine if any components should be de-configured or serviced.
2. Deferred error; hardware partially dealt with the problem via containment.
  - Operationally, action optional, because program flow has not been affected. However, steps may be taken by software to prevent access to the data in error.
  - Diagnostically, software may collect information to determine if any components should be de-configured or serviced.
3. Corrected error; hardware dealt with the problem.
  - Operationally, no action required, because program flow is unaffected.
  - Diagnostically, software may collect information to determine if any components should be de-configured or serviced.

Machine check conditions can be simulated to aid in debugging machine check handlers. See [2.14.3 \[Error Injection and Simulation\]](#) for more detail.

### 2.14.1.3 Error Detection, Action, Logging, and Reporting

Error detection is controlled by the MASK registers:

- Error detection for MCA controlled errors is enabled if not masked by MCi\_CTL\_MASK (see [Table 65 \[MCA register cross-reference table\]](#)).
- Error masking is performed regardless of MCA bank enablement in MCG\_CTL ([MSR0000\\_017B](#)).

Error action refers to the hardware response to an error, aside from logging and reporting. Enablement of error action for each error is enumerated in the EAC (Error Action Condition) column of the error descriptions tables as follows:

- D: Detected. The error action is taken if the error is detected (i.e., not masked). These actions occur regardless of whether the MCA bank is enabled in MCG\_CTL.
- E: Enabled. The error action is taken if the error is detected and the bank is enabled in MCG\_CTL.

Error logging refers to the storing of information in the status registers, and is enabled if all of the following are true:

- Error detection is enabled.
- The MCA bank is enabled in MCG\_CTL.

Error reporting refers to active notification of errors to software via machine check exceptions, and is enabled if all of the following are true:

- Error logging is enabled.
- The corresponding enable bit for the error in MCI\_CTL is set to 1.

A machine check exception will be generated if all the following are true:

- The error is uncorrected.
- The error is enabled for reporting.
- CR4.MCE is enabled.

Notes:

1. If CR4.MCE is clear, an error configured to cause a machine check exception will cause a shutdown.
2. If error reporting is disabled, the setting of CR4.MCE has no effect.
3. If an uncorrected error is disabled from reporting, containment of the error and logging/reporting of subsequent errors may be affected. Therefore, unmasked uncorrected errors should be enabled for reporting for normal operation. Uncorrected errors should only be disabled from reporting for debug purposes.
4. Errors not associated with a specific core are reflected to core 0 of the compute unit. The error description tables identify which errors are associated or not associated with a specific core of the compute unit.

Throughout the MCA register descriptions, the terms “enabled” and “disabled” generally refer to reporting, and the terms “masked” and “unmasked” generally refer to logging, unless otherwise noted.

Some logged errors increment a counter in MCI\_MISC, which may trigger an interrupt (see [2.14.1.7 \[Error Thresholding\]](#)). Although no machine check exception will be generated, these notifications can be viewed as “correctable machine check interrupts”.

For debug observability only, [D18F3x180\[ConvertUnCorToCorErrEn\]](#) can be used to log NB uncorrected errors as corrected errors.

#### 2.14.1.3.1 MCA conditions that cause Shutdown

The following architectural conditions cause the processor to enter the Shutdown state; see section “Machine-Check Errors” in APM volume 2 for more detail; see [1.2 \[Reference Documents\]](#):

- Attempting to generate an MCE when machine check reporting is disabled at the system level (CR4.MCE=0).
- Attempting to generate an MCE when a machine check is in progress on the same core ([MSR0000\\_017A\[MCIP\]](#)=1).

The following non-architectural conditions cause the processor to enter the Shutdown state:

- On MCA interrupts, if two or more uncorrected errors occur across MCA banks.

#### 2.14.1.3.2 Error Logging During Overflow

An error to be logged when the status register contains valid data can result in an overflow condition. During error overflow conditions, the new error may not be logged or an error which has already been logged in the status register may be overwritten. For the rules on error overflow, priority, and overwriting, see [MSR0000\\_0401\[Overflow\]](#).

Overflow alone does not indicate a shutdown condition. Uncorrected errors require software intervention. Therefore, when an uncorrected error cannot be logged, critical error information may have been lost, and MCI\_STATUS[PCC] may be set. If PCC is indicated, software should terminate system processing to prevent

data corruption (see [2.14.1.6 \[Handling Machine Check Exceptions\]](#)). If PCC is not indicated, any MCA data lost due to overflow was informational only and not critical to system hardware operation.

**Table 66: Overwrite Priorities for All Banks**

|             |             |          | Older Error    |                |           |           |
|-------------|-------------|----------|----------------|----------------|-----------|-----------|
|             |             |          | Uncorrected    |                | Corrected |           |
|             |             |          | Enabled        | Disabled       | Enabled   | Disabled  |
| Newer Error | Uncorrected | Enabled  | - <sup>1</sup> | - <sup>1</sup> | Overwrite | Overwrite |
|             |             | Disabled | - <sup>1</sup> | - <sup>1</sup> | Overwrite | Overwrite |
|             | Corrected   | Enabled  | -              | -              | -         | -         |
|             |             | Disabled | -              | -              | -         | -         |

#### 2.14.1.4 MCA Initialization

The following initialization sequence must be followed:

- MCI\_CTL\_MASK registers (see [Table 65 \[MCA register cross-reference table\]](#) for list):
  - BIOS must initialize the mask registers to inhibit error detection prior to the initialization of MCI\_CTL and [MSR0000\\_017B](#).
  - BIOS must not clear MASK bits that are reset to 1.
- The MCI\_CTL registers must be initialized by the operating system prior to enabling the error reporting banks in MCG\_CTL.

If initializing after a cold reset (see [D18F0x6C\[ColdRstDet\]](#)), then BIOS must clear the MCI\_STATUS MSRs. If initializing after a warm reset, then BIOS should check for valid MCA errors and if present save the status for later diagnostic use (see [2.14.1.6 \[Handling Machine Check Exceptions\]](#)).

BIOS may initialize the MCA without setting CR4.MCE; this will result in a system shutdown on any machine check which would have caused a machine check exception (followed by a reboot if configured in the chipset). Alternatively, BIOS that wishes to ensure continued operation in the event that a machine check occurs during boot may write MCG\_CTL with all ones and write zeros into each MCI\_CTL. With these settings, a machine check error will result in MCI\_STATUS being written without generating a machine check exception or a system shutdown. BIOS may then poll MCI\_STATUS during critical sections of boot to ensure system integrity. Before passing control to the operating system, BIOS should restore the values of those registers to what the operating system is expecting. (Note that using MCI\_CTL to disable error reporting on uncorrected errors may affect error containment; see [2.14.1.3 \[Error Detection, Action, Logging, and Reporting\]](#).)

Before ECC memory has been initialized with valid ECC check bits, BIOS must ensure that no memory operations are initiated if MCA reporting is enabled. This includes memory operations that may be initiated by hardware prefetching or other speculative execution. It is recommended that, until all of memory has been initialized with valid ECC check bits, the BIOS either does not have any valid MTRRs specifying a DRAM memory type or does not enable DRAM ECC machine check exceptions.

#### 2.14.1.5 Error Code

The MCI\_STATUS[ErrorCode] field contains information used to identify the logged error. [Table 67 \[Error Code Types\]](#) identifies how to decode ErrorCode. The MCI\_STATUS[ErrorCodeExt] field contains detailed, model-specific information that is used to further narrow identification for error diagnosis, but not error handling by software; see [2.14.1.6 \[Handling Machine Check Exceptions\]](#).

For a given error-reporting bank, Error Code Type is used in conjunction with the Extended Error Code (MCi\_STATUS[ErrorCodeExt]) to uniquely identify the Error Type; the value of ErrorCodeExt is unique within Error Code Type. Details for each Error Type are described in the tables accompanying the MCi\_STATUS register for each bank.

- MC0 (DC); [Table 196 \[MC0 Error Signatures\]](#).
- MC1 (IC); [Table 199 \[MC1 Error Signatures\]](#).
- MC2 (BU); [Table 202 \[MC2 Error Signatures\]](#)
- MC4 (NB); [Table 205 \[MC4 Error Signatures, Part 1\]](#) and [Table 206 \[MC4 Error Signatures, Part 2\]](#).
- MC5 (FR); [Table 214 \[MC5 Error Signatures\]](#).

**Table 67: Error Code Types**

| Error Code          | Error Code Type       | Description                                                                                                                                                          |

#### 2.14.1.6 Handling Machine Check Exceptions

A machine check handler is invoked to handle an exception for a particular core. Because MCA registers are generally not shared among cores, the handler does not need to coordinate register usage with handler instances on other cores. Those few MCA registers which are shared are noted in the register description. (See also [2.4.2.1 \[Registers Shared by Cores in a L2 complex\].](#))

For access to the core MC2 registers, [MSRC001\\_10A0\[McaToMstCoreEn\]](#) allows a single core to access the registers through MSR space without contention from other cores. This organization of registers on a per core basis allows independent execution, simplifies exception handling, and reduces the number of conditions which are globally fatal.

For access to the NB MCA registers, [D18F3x44\[NbMcaToMstCpuEn\]](#) allows a single core (the NBC) to access the registers through MSR space without contention from other cores. This organization of registers on a per core basis allows independent execution, simplifies exception handling, and reduces the number of conditions which are globally fatal.

At a minimum, the machine check handler must be capable of logging error information for later examination. The handler should log as much information as is needed to diagnose the error.

More thorough exception handler implementations can analyze errors to determine if each error is recoverable by software. If a recoverable error is identified, the exception handler can attempt to correct the error and restart the interrupted program. An error may not be recoverable for the process or virtual machine it directly affects, but may be containable, so that other processes or virtual machines in the system are unaffected and system operation is recovered; see [2.14.1.6.1 \[Differentiation Between System-Fatal and Process-Fatal Errors\]](#).

Machine check exception handlers that attempt to recover must be thorough in their analysis and the corrective actions they take. The following guidelines should be used when writing such a handler:

- Data collection:
  - All status registers in all error reporting banks must be examined to identify the cause of the machine check exception.
    - Read [MSR0000\\_0179\[Count\]](#) to determine the number of status registers visible to the core. The status registers are numbered from 0 to one less than the value found in [MSR0000\\_0179\[Count\]](#). For example, if the Count field indicates five status registers are supported, they are numbered MC0\_STATUS to MC4\_STATUS. These are generically referred to as MCi\_STATUS.
    - Check the valid bit in each status register (MCi\_STATUS[Val]). The remainder of the status register should be examined only when its valid bit is set.
    - When identifying the error condition and determining how to handle the error, portable exception handlers should examine the following MCi\_STATUS fields: ErrorCode, UC, PCC, CECC, UECC, Deferred, Poison. The expected settings of these and other fields in MCi\_STATUS are identified in the error signatures tables which accompany the descriptions of each MCA status register. See [2.14.1.5 \[Error Code\]](#) for a discussion of error codes and pointers to the error signatures tables.
      - MCi\_STATUS[ErrorCodeExt] should generally not be used by portable code to identify the error condition because it is model specific. ErrorCodeExt is useful in determining the error sub-type for root cause analysis.
    - Error handlers should collect all available MCA information (status register, address register, miscellaneous register, etc.), but should only interrogate details to the level which affects their actions. Lower level details may be useful for diagnosis and root cause analysis, but not for error handling.
- Recovery:
  - Check the valid MCi\_STATUS registers to see if error recovery is possible.
    - Error recovery is not possible when the processor context corrupt indicator (MCi\_STATUS[PCC]) is set to 1.
      - The error overflow status indicator (MCi\_STATUS[Overflow]) does not indicate whether error recovery is possible. See [2.14.1.3.2 \[Error Logging During Overflow\]](#).
    - If error recovery is not possible, the handler should log the error information and return to the operating system for system termination.
  - Check MCi\_STATUS[UC] to see if the processor corrected the error. If UC is set, the processor did not correct the error, and the exception handler must correct the error prior to attempting to restart the interrupted program. If the handler cannot correct the error, it should log the error information and return to the operating system. If the error affects only process data, it may be possible to terminate only the affected process or virtual machine. If the error affects processor state, continued use of that processor should not occur. See individual error descriptions for further guidance.

- If [MSR0000\\_017A\[RIPV\]](#) is set, the interrupted program can be restarted reliably at the instruction pointer address pushed onto the exception handler stack if any uncorrected error has been corrected by software. If RIPV is clear, the interrupted program cannot be restarted reliably, although it may be possible to restart it for debugging purposes. As long as PCC is clear, it may be possible to terminate only the affected process or virtual machine.
- When logging errors, particularly those that are not recoverable, check [MSR0000\\_017A\[EIPV\]](#) to see if the instruction pointer address pushed onto the exception handler stack is related to the machine check. If EIPV is clear, the address is not ensured to be related to the error.
- See [2.14.1.6.1 \[Differentiation Between System-Fatal and Process-Fatal Errors\]](#) for more explanation on the relationship between PCC, RIPV, and EIPV.
- Exit:
  - When an exception handler is able to successfully log an error condition, clear the `MCi_STATUS` registers prior to exiting the machine check handler. Software is responsible for clearing at least `MCi_STATUS[Val]`.
  - Prior to exiting the machine check handler, be sure to clear [MSR0000\\_017A\[MCIP\]](#). MCIP indicates that a machine check exception is in progress. If this bit is set when another machine check exception occurs in the same core, the processor enters the shutdown state.

Additional machine check handler portability can be added by having the handler use the `CPUID` instruction to identify the processor and its capabilities. Implementation specific software can be added to the machine check exception handler based on the processor information reported by `CPUID`.

In cases where sync flood is the recommended response to a particular error, a machine check exception cannot be used in lieu of the sync flood to stop the propagation of potentially bad data.

#### 2.14.1.6.1 Differentiation Between System-Fatal and Process-Fatal Errors

The bits `MCi_STATUS[PCC]`, [MSR0000\\_017A\[RIPV\]](#), and [MSR0000\\_017A\[EIPV\]](#) form a hierarchy, used by software to determine the degree of corruption and recoverability in the system.

[Table 74](#) shows how these bits are interpreted.

**Table 74: Error Scope Hierarchy**

| PCC | UC | RIPV | EIPV | Deferred | Poison | Comments                                                                                                                                                                                                   |
|-----|----|------|------|----------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1   | 1  | -    | -    | -        | -      | <b>System fatal error.</b> Signaled via machine check exception, action required. Error has corrupted system state (PCC=1). The error is fatal to the system and the system processing must be terminated. |
| 0   | 1  | 1    | 1    | -        | -      | <b>RIPV=1, EIPV=0: Should not occur.</b> Restartable errors will indicate the instruction in error in EIP.                                                                                                 |

**Table 74: Error Scope Hierarchy**

| PCC | UC | RIPV | EIPV | Deferred | Poison | Comments                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----|----|------|------|----------|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The error is confined to the process, however the process cannot be restarted even if the uncorrected error is corrected by software.<br><br>Poison=1; the error is due to consumption of poison data. If the affected process or virtual machine is terminated, the system may continue operation.            |
| 0   | 0  | -    | -    | 1        | 0      | <b>Deferred error.</b> Action optional. A latent error has been discovered, but not yet consumed; a machine check exception will be generated if the affected data is consumed. Error handling software may attempt to correct this data error, or prevent access by processes which map the data, or make the physical resource containing the data inaccessible.<br>Note: May be detected on a demand access or a scrub access. |
| 0   | 0  | -    | -    | 0        | 0      | <b>Corrected error.</b><br>Signaled via error thresholding mechanisms (2.14.1.7 [Error Thresholding]); no action required.                                                                                                                                                                                                                                                                                                        |

### 2.14.1.7 Error Thresholding

For some types of errors, the hardware maintains counts of the number of errors. When the counter reaches a programmable threshold, an event may optionally be triggered to signal software. This is known as error thresholding. The primary purpose of error thresholding is to help software recognize an excessive rate of errors, which may indicate marginal or failing hardware. This information can be used to make decisions about deconfiguring hardware or scheduling service actions. Counts are incremented for corrected, deferred, and uncorrected errors.

The error thresholding hardware counts only the number of errors; it is up to software to track the errors reported over time in order to determine the rate of errors. Thresholding gives error counts on groups of resources. In order to make decisions on individual resources, a finer granularity of error information, such as MCA information for specific errors, must be utilized in order to obtain more accurate counts and to limit the scope of actions to affected hardware.

Thresholding is performed for “Error Threshold Groups” identified in the list below. For all error threshold groups, some number of corrected errors is expected and normal. There are numerous factors influencing error rates, including temperature, voltage, operating speed, and geographic location. The determination of expected error rates is heuristic, with recommended error rates defined below. Although these recommendations are deliberately conservative, they may need to be adjusted if operating in extreme conditions. In addition, the normal error rates are for long term averages and it may not be abnormal for bursts to occur. In order to accommodate the various factors, including software latency to respond and track the error thresholding, additional guardband above the normal rates is recommended before error rates are considered abnormal for purposes of hardware action. These recommendations are for error thresholding purposes, and are not design parameters.

The {MC0, MC1, MC2, MC5} error thresholding banks maintains counters, but do not provide interrupts when the threshold is reached; these counters must be polled.

Error thresholding groups:

- DRAM (MC4)
  - Memory errors are counted and polled or reported via [MSR0000\\_0413](#).
  - DRAM errors are the errors listed in [Table 204 \[MC4 Error Descriptions\]](#) as “D” (DRAM) in the ETG (Error Threshold Group) column.
  - Operating systems can avoid or stop using memory pages with excessive errors.
- Links (MC4)
  - Link errors are counted and reported via [MSRC000\\_0408](#).
  - Link errors are the errors listed in [Table 204 \[MC4 Error Descriptions\]](#) as “L” (Cache) in the ETG (Error Threshold Group) column.
  - For a link exhibiting excessive errors, it may be possible to reduce errors by lowering the link frequency or reducing the link width (if a bad lane can be avoided). See [2.11 \[Root Complex\]](#) for details and restrictions on configuring links.

In rare circumstances, such as two simultaneous errors in the same error thresholding group, it is possible for one error not to increment the counter. In these conditions, MCi\_STATUS[Overflow] may indicate that an overflow occurred, but the error counter may only indicate one error.

### 2.14.1.8 Scrub Rate Considerations

This section gives guidelines for the scrub rate settings available in [D18F3x58 \[Scrub Rate Control\]](#) and [MSRC001\\_10A0 \[L2I Configuration \(L2I\\_CFG\)\]](#). Scrubbers are used to periodically read cacheline sized data locations and associated tags. There are two primary benefits to scrubbing. First, scrubbing corrects any corrected errors which are discovered before they can migrate into uncorrected errors. This is particularly important for soft errors, which are caused by external sources such as radiation and which are temporary conditions which do not indicate malfunctioning hardware. Second, scrubbers help identify marginal or failed hardware by finding and logging repeated errors at the same locations (see also [2.14.1.7 \[Error Thresholding\]](#)).

There are many factors which influence scrub rates. Among these are:

- The size of memory or cache to be scrubbed (higher rate for larger size)
- Resistance to upsets (higher rates for more sensitive technologies and lower voltages)
- Geographic location and altitude (higher rate for higher flux density of cosmic radiation)
- Alpha particle contribution of packaging (higher rate for less pure packaging)
- Performance sensitivity (lower rate for more performance sensitivity)
- Risk aversion (higher rate for higher risk aversion)

The baseline recommendations in [Table 75](#) are intended to provide excellent protection at most geographic locations, while having no measurable effect on performance or power consumption. DRAM: F3x58[DramScrub] should be set to scrub all of memory every 24 hours, unless other guidelines are given by the DRAM vendor. Adjustments may be necessary due to special circumstances. Refer to JEDEC standards for guidelines on adjusting for geographic location.

**Table 75: Recommended Scrub Rates per Node**

| Register                                          | Memory Size per Node (GB) | Register Setting | Scrub Rate |
|---------------------------------------------------|---------------------------|------------------|------------|
| <a href="#">MSRC001_10A0</a> [L2ScrubberInterval] | -                         | 100h             | 98.6 ms    |

**Table 75: Recommended Scrub Rates per Node**

|                     | 32 GB < Size <= 64 GB     | 0Ch              | 81.9 us    |
|                     | 64 GB < Size <= 128 GB    | 0Bh              | 41.0 us    |
|                     | 128 GB < Size <= 256 GB   | 0Ah              | 20.5 us    |
|                     | 256 GB < Size             | 09h              | 10.2 us    |

For steady state operation, finding a range of useful scrub rates may be performed by selecting a scrub rate which is high enough to give good confidence about protection from accumulating errors and low enough that it has no measurable effect on performance. The above baselines are made to maximize error coverage without affecting performance and not based on specific processor soft error rates.

For low power states in which the processor core is halted, the power management configuration may affect scrubbing; see [2.8.3 \[Memory Scrubbers\]](#).

#### 2.14.1.9 Error Diagnosis

This section describes generalized information and algorithms for diagnosing errors. The primary goal of diagnosis is to identify the failing component for repair purposes. The secondary goal is to identify the smallest possible sub-component for deallocation, deconfiguration, or design/manufacturing root cause analysis.

*Indictment* means identifying the part in error. The simplest form of indictment is *self-indictment*, where the bank reporting the error is the faulty unit. The next simplest form of indictment is *eyewitness indictment*, where the faulty unit is not the bank reporting the error, but is identified unambiguously. Both of these forms can be considered direct indictment; the information for indictment is contained in the MCA error information. If an error is not directly indicted, then identifying the faulty unit is more difficult and may not be an explicit part of the error log.

In general, an address logged in the MCA is useful for direct indictment only if the address identifies a physical location in error, such as a cache index. Logical addresses, while identifying the data, do not identify the location of the data.

If possible, physical storage locations in caches should be checked to determine whether the error is a soft error (a temporary upset of the stored value) or a hard fault (malfunctioning hardware). A location which has had a soft error can be corrected by writing a new value to the location; a reread of the location should see the new value. Hard faults cannot be corrected by writing a new value; the hardware persistently returns the previous value. If such checking is not possible, a grossly simplifying assumption can be made that uncorrected errors are hard and corrected errors are soft. Repeated corrected errors from the same location are an indication that the fault is actually hard.

Determining whether corrected errors represent a hard fault or a soft error requires understanding the access

patterns and any attempts to correct the faulty data in place. An attempt to correct the data in place creates two *epochs*, one before the correction event, and one after. If an error is seen at the same location in two different epochs (especially back-to-back epochs), it is more likely that the cause is a hard fault, since the error has persisted or repeated through an in place correction. The more epochs in which a error is seen, the higher the likelihood of it being caused by a hard fault.

As an example, consider a corrected error found during a read from DRAM. If the DRAM redirect scrubber is enabled (**D18F3x5C**[ScrubReDirEn]), the data in error is corrected in place, and this event conceptually creates a new epoch. If the original fault was due to a soft error, a read of the same data in the new epoch should not encounter a data error. If the original fault was due to a hard fault (e.g., a stuck bit), a read of the data in the new epoch will likely result in another corrected or uncorrected error.

There are numerous correction events that can be used to separate time periods into epochs. These include DRAM redirect scrubs, DRAM sequential scrubs, cache scrubs, cache writes, cache flushes, resets, and others.

#### 2.14.1.9.1 Common Diagnosis Information

A common set of diagnosis information is useful for many problems. [Table 76](#) indicates the minimum set of generally useful diagnostic information that should be collected by software, unless the specifics of the problem are known to be narrower, based on the error code or other information.

It is useful to collect configuration information to ensure that the behavior is not caused by misconfiguration.

**Table 76: Registers Commonly Used for Diagnosis**

| MCA Bank | Status                                                                               | Configuration                                                                                             |
|----------|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|

| MC1      | MSR0000_0405<br>MSR0000_0406<br>MSR0000_0407                                         | MSR0000_0404<br>MSRC001_1021                                                                              |
| MC2      | MSR0000_0409<br>MSR0000_040A<br>MSR0000_040B                                         | MSR0000_0408<br>MSRC001_0046<br>MSRC001_1023                                                              |
| MC3      | Reserved                                                                             | Reserved                                                                                                  |
| MC4      | MSR0000_0411<br>MSR0000_0412<br>MSR0000_0413<br>MSRC000_0408<br>D18F3x54<br>D18F2xAC | MSR0000_0410<br>MSRC001_0048<br>D18F3x40<br>D18F3x44<br>D18F3xE4<br>D18F3xE8<br>MSRC001_001F<br>D18F3x188 |
| MC5      | MSR0000_0415<br>MSR0000_0416<br>MSR0000_0417                                         | MSR0000_0414<br>MSRC001_1020                                                                              |

If examining MCA registers after startup, determine the cause of the startup:

- INIT; [D18F0x6C](#)[InitDet].
- Cold reset; [D18F0x6C](#)[ColdRstDet].
- Warm reset; if not INIT or cold reset.

To see if a link failure occurred, examine [D18F0x\[E4,C4,A4,84\]](#)[LinkFail]. If set, look for additional information:

- Receipt of a sync, such as during a sync flood, saves a status of Sync Error in MC4\_STATUS.
- CRC error saves a status of CRC Error in MC4\_STATUS. See [D18F0x\[E4,C4,A4,84\]](#)[CrcErr,CrcFloodEn].
- Link not present does not save status in MC4\_STATUS. See [D18F0x\[E4,C4,A4,84\]](#)[InitComplete].

Other registers may be needed depending on the specific error symptoms.

## 2.14.2 DRAM ECC Considerations

DRAM is protected by an error correcting code (ECC). The DRAM error correcting code features an ECC word formed by a symbol based code. The x4 code uses thirty-six 4-bit symbols to make a 144-bit ECC word made up of 128 data bits and 16 check bits.

The x4 code is a single symbol correcting (SSC) and a double symbol detecting (DSD) code. This means the x4 code is able to correct 100% of single symbol errors (any bit error combination within one symbol), and detect 100% of double symbol errors (any bit error combination within two symbols).

### 2.14.2.1 ECC Syndromes

For memory errors, the sections below describe how to find the DIMM in error. The process varies slightly according to the ECC code in use. To determine which ECC code is being used, see [D18F3x180](#)[EccSymbolSize].

For correctable errors, the DIMM in error is uniquely identified by the error address ([MSR0000\\_0412](#)[ErrAddr]) and the ECC syndrome ([MSR0000\\_0411](#)[Syndrome[15:8]] and [MSR0000\\_0411](#)[Syndrome[7:0]]). The error address maps to the two DIMMs composing the 128-bit line, and the ECC syndrome identifies one DIMM by identifying the symbol within the line.

#### 2.14.2.1.1 x4 ECC

The use of x4 ECC is indicated in [D18F3x180](#)[EccSymbolSize].

The syndrome field uniquely identifies the failing bit positions of a correctable ECC error. Only syndromes identified by [Table 77](#) are correctable by the error correcting code.

Symbols 00h-0Fh map to data bits 0-63; symbols 10h-1Fh map to data bits 64-127; symbols 20-21h map to ECC check bits for data bits 0-63; symbols 22-23h map to ECC check bits for data bits 64-127.

To use [Table 77](#), first find the 16-bit syndrome value in the table. This is performed by using low order 4 bits of the syndrome to select the appropriate error bitmask column. The entire four digit syndrome should then be in one of the rows of that column. The Symbol In Error row indicates which symbol, and therefore which DIMM has the error, and the column indicates which bits within the symbol. To map to the DIMM, use the algorithm in [2.10.5 \[Routing DRAM Requests\]](#).

For example, if the ECC syndrome is 6913h, then symbol 05h has the error, and bits 0 and 1 within that symbol are corrupted, since the syndrome is in column 3h (0011b). Symbol 05h maps to bits 23-20, so the corrupted bits are 20 and 21.

**Table 77: x4 ECC Correctable Syndromes**

| Symbol<br>In Error | Error Bitmask |      |      |      |      |      |      |      |      |      |      |      |      |      |      |

### 2.14.3 Error Injection and Simulation

*Error injection* allows the introduction of errors into the system for test and debug purposes. See the following sections for error injection details:

- DRAM: See [2.14.3.1 \[DRAM Error Injection\]](#).
- Link:
  - [D18F3x44](#)[GenLinkSel, GenSubLinkSel, GenCrcErrByte1, GenCrcErrByte0].

*Error simulation* involves creating the appearance to software that an error occurred, and can be used to debug machine check interrupt handlers. This is performed by manually setting the MCA registers with desired values, and then driving the software via INT18. See [MSRC001\\_0015](#)[McStatusWrEn] for making MCA registers writable for non-zero values. When McStatusWrEn is set, privileged software can write non-zero values to the specified registers without generating exceptions, and then simulate a machine check using the INT18 instruction (INTn instruction with an operand of 18). Setting a reserved bit in these registers does not generate an exception when this mode is enabled. However, setting a reserved bit may result in undefined behavior.

#### 2.14.3.1 DRAM Error Injection

This section gives details and examples on injecting errors into DRAM using [D18F3xBC\\_x8](#) [DRAM ECC]. The intent of DRAM error injection is to cause a discrepancy between the stored data and the stored ECC value. Therefore, DRAM error injection is only possible on DRAM which supports ECC, and in which [D18F2x90\\_dct\[0\]](#)[DimmEccEn] and [D18F3x44](#)[DramEccEn] are set.

The memory subsystem operates on 64-byte cachelines. The following fields are used to set how the cacheline is to be corrupted in DRAM:

- [D18F3xB8](#)[ArrayAddress] selects a cacheline quadrant (16-byte section) of the cacheline. Each cacheline quadrant is protected by an ECC word. Note that there are special requirements for which bits are used to specify the target quadrant.
- [D18F3xBC\\_x8](#)[ErrInjEn] selects a 16-bit word of the cacheline quadrant selected in ArrayAddress. The 16-bit word identified as ECC[15:0] refers to the bits which store the ECC value; the other 16-bit words address the data on which the ECC is calculated. One or more of these 16-bit words can be selected, and the error bitmask indicated in EccVector is applied to each of the selected words.
- [D18F3xBC\\_x8](#)[EccVector] is a bitmask which selects the individual bits to be corrupted in the 16-bit words selected by ErrInjEn. When selecting the bits to be corrupted for correctable or uncorrectable errors, consider the ECC scheme being used, including symbol size; see [2.14.2 \[DRAM ECC Considerations\]](#) for more details. Note that corrupting more than two symbols may exceed the limits of the ECC to detect the errors; for testing purposes it is recommended that no more than two symbols be corrupted in a single cacheline quadrant.

The distinction between [D18F3xBC\\_x8](#)[DramErrEn] and [D18F3xBC\\_x8](#)[EccWrReq] is that DramErrEn is used to continuously inject errors on every write. This bit is set and cleared by software. EccWrReq is used to inject an error on only one write. This bit is set by software and is cleared by hardware after the error is

injected.

When performing DRAM error injection on multi-node systems, [D18F3xB8](#) and [D18F3xBC\\_x8](#) of the NB to which the memory is attached must be programmed.

The following can be used to trigger the injection:

- For implicit addressing, the memory address is not an explicit parameter of the error injection interface. Once the error injection registers [D18F3xB8](#) and [D18F3xBC](#) are set, the next non-cached access of the appropriate type will trigger the mechanism and apply it to the accessed address. The access should be non-cached so that it is ensured to be seen by the memory controller. Possible methods to ensure a non-cached access include using the appropriate MTRR to set the memory type to UC or turning off caches. If it is important to know the address, then system activity must be quiesced so that the access can take place under careful software control. Once the error injection pattern is set in [D18F3xB8](#) and [D18F3xBC\\_x8](#):
  - Set either [D18F3xBC\\_x8\[EccWrReq\]](#) or [D18F3xBC\\_x8\[DramErrEn\]](#) to enable the triggering mechanism.
  - The next non-cached access of the appropriate type will trigger the mechanism and apply it to the accessed address.

After the error is injected, the data must be accessed in order for the error detection to be triggered. The error address logged in [MSR0000\\_0412](#) will correspond to the cacheline quadrant that contains the error.

When using [MSR0000\\_0411](#) to read MC4\_STATUS after an error injection and subsequent error detection, be aware that the setting of [D18F3x44\[NbMcaToMstCpuEn\]](#) can cause different cores to see different values. Alternatively, MC4\_STATUS can be read through the PCI-defined configuration space aliases [D18F3x4C](#) and [D18F3x48](#), which do not return different values to different cores, regardless of the setting of [D18F3x44\[NbMcaToMstCpuEn\]](#).

**Example 1:** Injecting a correctable error with implicit addressing:

- Program error pattern:
  - [D18F3xB8\[ArraySelect\]](#)=1000b // select DRAM as target
  - [D18F3xB8\[ArrayAddress\]](#)=000000000b // select 16-byte (128-bit) section
  - [D18F3xBC\\_x8\[ErrInjEn\]](#)=000000001b // select 16-bit word in 16-byte section
  - [D18F3xBC\\_x8\[EccRdReq\]](#)=0 // not a read request
  - [D18F3xBC\\_x8\[EccVector\]](#)=0001h // set bitmask to inject error into only one symbol
- Program error trigger:
  - [D18F3xBC\\_x8\[DramErrEn\]](#)=0 // inject only a single error
  - [D18F3xBC\\_x8\[EccWrReq\]](#)=1 // a write request; enable injection on next write
- Clean up // if programmed for continuous errors
  - [D18F3xBC\\_x8\[DramErrEn\]](#)=0 // inject only a single error

## 2.15 Fusion Controller Hub

The processor contains an integrated Fusion Controller Hub (FCH). The FCH supports the following interfaces:

- Universal Serial Bus (USB) versions 1.1, 2.0, and 3.0
- Serial ATA revision 3.0
- Secure Digital (SD)
- System Management Bus (SMBus)
- Low Pin Count (LPC) bus and SPI interface
- High Definition (HD) audio
- Serial IRQ
- Serial Peripheral Interface (SPI) ROM
- Advanced Configuration and Power Interface (ACPI)

The FCH also comprises the following functions:

- Real-Time Clock (RTC)
- Programmable Interrupt Controller (PIC)
- System clock generation
- System Management Interrupt (SMI)
- General-Purpose I/O (GPIO)
- Power management
- Watchdog Timer (WDT)

### 2.15.1 MMIO Programming for Legacy Devices

The legacy devices LPC, IOAPIC, ACPI, TPM and Watchdog Timer require the base address of the Memory Mapped IO registers to be assigned before these logic blocks are accessed. The Memory Mapped IO register base address and its entire range should be mapped to non-posted memory region by programming the CPU register. See BIOS Developer's Guide for details.

### 2.15.2 USB Controllers

The processor supports ten USB ports using the BP\_USB\_HSD[9:0]P/N pins. Ports 0 through 7 are compatible with USB 2.0 (EHCI) and USB 1.1 (OHCI). Ports 8 and 9 are connected to an EHCI/OHCI controller pair or to an xHCI controller, as specified by [PMxEF\[PortRoutingSelect\]](#). The xHCI controller operates at USB 1.1, USB 2.0, or USB 3.0 speeds. Support for USB 3.0 varies by product; see [PMxD9\\_x03\[XhcDis\]](#).

When ports 8 and 9 are connected to the xHCI controller, these ports are accessed using either the BP\_USB\_HSD[9,8]P/N pins (USB 1.1 and USB 2.0) or the BP\_USB\_SS[1,0][RX,TX]P/N pins (USB 3.0). When ports 8 and 9 are connected to an EHCI/OHCI controller pair, only the BP\_USB\_HSD[9,8]P/N pins are used.

**Table 78: USB Port Mapping**

| Ports | <a href="#">PMxEF[PortRoutingSelect]</a> | USB Version | Controller | Registers          | Pins               |
|-------|------------------------------------------|-------------|------------|--------------------|--------------------|
| 3-0   | X                                        | 1.1         | OHCI 1     | D12F0xXX, OHCI1xXX | BP_USB_HSD[3:0]P/N |
|       |                                          | 2.0         | EHCI 1     | D12F2xXX, EHCI1xXX |                    |

**Table 78: USB Port Mapping**

| Ports | PMxEF[PortRoutingSelect] | USB Version | Controller | Registers                           | Pins                     |
|-------|--------------------------|-------------|------------|-------------------------------------|--------------------------|
| 7-4   | X                        | 1.1         | OHCI 2     | D13F0xXX, OHCI2xXX                  | BP_USB_HSD[7:4]P/N       |
|       |                          | 2.0         | EHCI 2     | D13F2xXX, EHCI2xXX                  |                          |
| 9-8   | 0                        | 1.1         | OHCI 3     | D16F0xXX, OHCI3xXX                  | BP_USB_HSD[9,8]P/N       |
|       |                          | 2.0         | EHCI 3     | D16F2xXX, EHCI3xXX                  |                          |
|       | 1                        | 1.1         | xHCI       | D10F0xXX, XHCI*<br>(See 3.26.4.3.2) | BP_USB_HSD[9,8]P/N       |
|       |                          | 2.0         |            |                                     |                          |
|       |                          | 3.0         |            |                                     | BP_USB_SS[1,0][RX,TX]P/N |

Refer to the following for the USB controller register definitions:

- Section 3.26.4.1 [USB 1.1 (OHCI)] for the OHCI controllers

### 2.15.2.1 USB Power Management

USB power management functions are controlled by registers outside the USB controller registers spaces.

See the following register definitions in 3.26.13 [Power Management (PM) Registers]:

- PMx80[UsbPeriodicalSetBmSts, Usb20SetBmSts, Usb11SetBmSts, Usb11BmStsEn]
- PMxED [USB Gating]
- PMxEF [USB Enable]
- PMxF0 [USB Control]

### 2.15.2.2 USB Interrupts

The interrupt mapping is specified by IOC00 [Pci\_Intr\_Index] and IOC01 [Pci\_Intr\_Data]. By default, USB interrupts are routed to PCI INTA#, B#, and C#.

For normal operations, MSI must be disabled in all OHCI and EHCI controllers.

### 2.15.2.3 BIOS Programming Requirements For USB Reset During S3 Resume

Set PMxF0[UsbKbResetEnable]=1 to enable the USB controller to get reset by any software that generates a PCIRST# condition (e.g. a keyboard reset or a write to IOCF9). To avoid losing the USB connection status during the S3 resume procedure, BIOS must ensure that PMxF0[UsbKbResetEnable]=0 before any software-generated PCIRST# reset condition during S3 resume.

### 2.15.2.4 Enabling the xHCI Controller

Software performs the following sequence to enable the xHCI controller:

1. Program PMxEF[Usb3OhciEnable]=0.
2. Program PMxEF[Usb3EhciEnable]=0.
3. Program PMxEF[PortRoutingSelect]=1.
4. Program XHCI\_PMx00[Xhci0Enable]=1.

### 2.15.2.5 OHCI Arbiter Mode

Software should program the following sequence for all OHCI controllers to set OHCI arbiter mode:

1. Whenever the system resumes from S3/S4/S5, software should reset the USB controllers as follows:
  - A. Program PMxD3[AssertUsbRstB]=0.

- B. Wait for <1 ms.
- C. Program `PMxD3[AssertUsbRstB]=1`.
- 2. Program `D[16,13,12]F0x80[OHCIArbiterMode]=11b`.
- 3. Program `D[16,13,12]F0x80[OHCIArbVldCtl]=1b`.

### 2.15.2.6 USB2.0 Controller PHY Configuration and Calibration

Software performs the following sequence to configure EHCI common PHY for each USB port to be used shortly after chip boot up and after USB2.0 EHCI controller initiated the calibration. The register settings have to be re-established to ensure USB2.0 PHY is properly calibrated. It is not needed after waking up from S3.

1. Program `HSSLEW=10b`.
  - A. Program `EHCI[3:1]xB4[PortNumber]` with the controller port number according to [Table 79](#).
  - B. Program `EHCI[3:1]xB4[VControlModeSel]=0110b`.
  - C. Program `HSSLEW` value at `EHCI[3:1]xB4[1:0]=10b`.
  - D. Program `EHCI[3:1]xB4[VLoadB]=1`.
  - E. Wait for `EHCI[3:1]xB4[VBusy]=0`.
  - F. Program `EHCI[3:1]xB4[VLoadB]=0`.
  - G. Wait for `EHCI[3:1]xB4[VBusy]=0`.
  - H. Program `EHCI[3:1]xB4[VLoadB]=1` to lock the PHY control interface.
2. Program `EHCI[3:1]xD0[BgAdj]=6`.
3. Program `EHCI[3:1]xC4[IRefAdj]=2`.
4. Program `EHCI[3:1]xC4[XRefAdj]=2`.
5. Program `EHCI[3:1]xC4[PVI]=1`.
6. Program `EHCI[3:1]xC4[CPAdj]=1`.
7. Program `EHCI[3:1]xC4[DLLControl]=90h`.
8. Program `EHCI[3:1]xD4[PllFilter]=1`.
9. Program `EHCI[3:1]xD4[CalEnable]=0`.
10. Wait for 200 ns.
11. Program `EHCI[3:1]xD4[CalEnable]=1`.
12. Wait for 400 ns.
13. Program `EHCI[3:1]xD4[CalEnable]=0`.

### 2.15.2.7 USB2.0 Controller ISO Device CRC False Error Detection

Software performs the following sequence to program CDR phase shift limit for each USB port to be used:

1. Program `EHCI[3:1]xB4[PortNumber]` with the controller port number according to [Table 79](#).
2. Program `EHCI[3:1]xB4[VControlModeSel]=0111b`.
3. Program `EHCI[3:1]xB4[2:0]=101b`.
4. Program `EHCI[3:1]xB4[VLoadB]=1`.
5. Wait for `EHCI[3:1]xB4[VBusy]=0`.
6. Program `EHCI[3:1]xB4[VLoadB]=0`.
7. Wait for `EHCI[3:1]xB4[VBusy]=0`.
8. Program `EHCI[3:1]xB4[VLoadB]=1` to lock the PHY control interface.

Table 79: USB Port to `EHCI[3:1]xB4[PortNumber]` Mapping

| USB Port | Software selects by programming      |
|----------|--------------------------------------|
| 0        | <code>EHCI1xB4[PortNumber]=0h</code> |
| 1        | <code>EHCI1xB4[PortNumber]=1h</code> |
| 2        | <code>EHCI1xB4[PortNumber]=2h</code> |

Table 79: USB Port to EHCI[3:1]xB4[PortNumber] Mapping

|   |                         |
|---|-------------------------|
| 3 | EHCI1xB4[PortNumber]=3h |
| 4 | EHCI2xB4[PortNumber]=0h |
| 5 | EHCI2xB4[PortNumber]=1h |
| 6 | EHCI2xB4[PortNumber]=2h |
| 7 | EHCI2xB4[PortNumber]=3h |
| 8 | EHCI3xB4[PortNumber]=0h |
| 9 | EHCI3xB4[PortNumber]=1h |

### 2.15.2.8 xHC USB2.0 Common PHY Calibration

The following programming sequence has to be carried out shortly after chip boot up and after USB2.0 EHCI/XHCI controller initiated the calibration. The register settings have to be re-established to ensure USB2.0 PHY is properly calibrated. It is not needed after waking up from S3.

1. Program HSSLEW=10b.
  - A. Program D10F0x4C\_x4000\_0000[PortNumber] with the controller port number according to Table 80.
  - B. Program D10F0x4C\_x4000\_0000[VControlModeSel]=0110b.
  - C. Program HSSLEW value at D10F0x4C\_x4000\_0000[1:0]=10b.
  - D. Program D10F0x4C\_x4000\_0000[VLoadB]=1.
  - E. Wait for D10F0x4C\_x4000\_0000[VBusy]=0.
  - F. Program D10F0x4C\_x4000\_0000[VLoadB]=0.
  - G. Wait for D10F0x4C\_x4000\_0000[VBusy]=0.
  - H. Program D10F0x4C\_x4000\_0000[VLoadB]=1 to lock the PHY control interface.
2. Program D10F0x4C\_x4000\_0050[BgAdj]=6.
3. Program D10F0x4C\_x4000\_000C[IRefAdj]=2.
4. Program D10F0x4C\_x4000\_000C[XRefAdj]=2.
5. Program D10F0x4C\_x4000\_000C[PVI]=1.
6. Program D10F0x4C\_x4000\_000C[CPAdj]=1.
7. Program D10F0x4C\_x4000\_000C[DllControl]=90h.
8. Program D10F0x4C\_x4000\_0054[PllFilter]=1.
9. Program D10F0x4C\_x4000\_0054[CalEnable]=0.
10. Wait for 200 ns.
11. Program D10F0x4C\_x4000\_0054[CalEnable]=1.
12. Wait for 400 ns.
13. Program D10F0x4C\_x4000\_0054[CalEnable]=0.

### 2.15.2.9 USB3.0 PHY Auto-Calibration Enablement

BIOS enables USB3.0 PHY auto-calibration as follows:

1. Program XHCI\_PMx8C[PllVcoTune[3:0]]=0011b.
2. Program XHCI\_PMx8C[CrPllCalibEn]=1.

### 2.15.2.10 xHCI ISO Device CRC False Error Detection

Software performs the following sequence to program CDR phase shift limit for each USB port to be used:

1. Program D10F0x4C\_x4000\_0000[PortNumber] with the controller port number according to Table 80.
2. Program D10F0x4C\_x4000\_0000[VControlModeSel]=0111b.
3. Program D10F0x4C\_x4000\_0000[2:0]=101b.

4. Program `D10F0x4C_x4000_0000[VLoadB]=1`.
5. Wait for `D10F0x4C_x4000_0000[VBusy]=0`.
6. Program `D10F0x4C_x4000_0000[VLoadB]=0`.
7. Wait for `D10F0x4C_x4000_0000[VBusy]=0`.
8. Program `D10F0x4C_x4000_0000[VLoadB]=1` to lock the PHY control interface.

Table 80: USB Port to `D10F0x4C_x4000_0000[PortNumber]` Mapping

| USB Port | Software selects by programming                 |
|----------|-------------------------------------------------|
| 8        | <code>D10F0x4C_x4000_0000[PortNumber]=0h</code> |
| 9        | <code>D10F0x4C_x4000_0000[PortNumber]=1h</code> |

### 2.15.2.11 xHCI PHY Clock Gating

The following programming sequence configures the clock gating in the xHCI PHY. They must be performed for each port after enabling xHCI controller and need to be restored after all power state resumes.

1. Program `D10F0x4C_x4000_0000[VLoadB]=1`.
2. Program `D10F0x4C_x4000_0000[PortNumber]` with the controller port number according to Table 80.
3. Program `D10F0x4C_x4000_0000[VControlModeSel]=0011b`.
4. Program `D10F0x4C_x4000_0000[2]=1`.
5. Read `D10F0x4C_x4000_0000[VBusy]` to ensure it is 0.
6. Program `D10F0x4C_x4000_0000[VLoadB]=0`.
7. Wait for `D10F0x4C_x4000_0000[VBusy]=0`.
8. Program `D10F0x4C_x4000_0000[VLoadB]=1` to lock the PHY control interface.

### 2.15.2.12 xHCI Firmware Preload

Software performs the following programming sequence for firmware preload. Firmware preload should be executed before BIOS de-asserts `XHCI_PMx00[U3CoreReset]`.

1. Enable firmware preload by programming `XHCI_PMx00[FwLoadMode]=1`.
2. Program `XHCI_PMx04[XhciFwPreloadType]` with 1 for boot RAM preload and 0 for instruction RAM preload.
3. Program `XHCI_PMx04[XhciFwRomAddr]` with the offset of the application firmware in the external ROM.
4. Program `XHCI_PMx08[XhciFwRamAddr]= 0`.
5. Program `XHCI_PMx08[XhciFwSize]=8000h`.
6. Program `XHCI_PMx00[FwPreloadStart]=1` to start firmware preload.
7. Wait for `XHCI_PMx00[FwPreloadComplete]=1`.
8. Program `XHCI_PMx00[FwPreloadStart]=0`.
9. Program `XHCI_PMx00[U3CoreReset]=0` to de-assert xHC reset.

### 2.15.2.13 xHCI Clear Pending PME on Sx State Entry

During S3/S4 entry with wake from Sx state enabled, if the xHCI controller received a wake event before the system shutdown into Sx state is completed, `D10F0x54[PmeStatus]` may remain set when the system enters into Sx state. This will prevent subsequent wake events from being propagated to the ACPI controller. BIOS should write 1 to clear `D10F0x54[PmeStatus]` if `D10F0x54[PmeStatus]` is 1 and ACPI GEvent status bit is clear on entry into S3/S4 state.

### 2.15.2.14 xHCI Enable OHCI3/EHCI3 on S4/S5 State Entry

If xHCI controller is enabled, OHCI3/EHCI3 controllers are disabled for normal operations. See [2.15.2.4 \[Enabling the xHCI Controller\]](#). On S4/S5 entry, OHCI3/EHCI3 controllers should be enabled to avoid possibly stalled IRQ1/IRQ12 interrupts, which could cause keyboard/mouse hang during wake up.

- Program [PMxEF\[Usb3OhciEnable\]](#)=1.
- Program [PMxEF\[Usb3EhciEnable\]](#)=1.

## 2.15.3 SATA

### 2.15.3.1 SATA Operating Mode

The SATA host controller can operate in the following modes:

- IDE mode.
- AHCI mode.

Software programs the subclass code and programming interface register to enable the SATA controller as RAID controller, IDE controller, or AHCI controller.

1. Program [D11F0x40\[SubclassCodeWriteEnable\]](#)=1.
2. Program [D11F0x08\[SubclassCode\]](#) and [D11F0x08\[ProgramIF\[7:0\]\]](#) according to [Table 230 \[SATA Controller Subclass Code and ProgramIF Settings\]](#).
3. Program [D11F0x40\[SubclassCodeWriteEnable\]](#)=0.

### 2.15.3.2 SATA Drive Detection in IDE mode

The following sequence should be included in the SBIOS drive identification loop for SATA drive detection in IDE mode.

1. If any of the SATA port status register at [SATAx1\[A,2\]8\[DET\]](#)==03h, program [IDE\[1:0\]x06\[DriveHead\]](#)=A0h for the corresponding port and go to Step 2.  
Else, no SATA drives are attached; exit the detection loop program.
2. If ([IDE\[1:0\]x06\[DriveHead\]](#)==A0h) && ([IDE\[1:0\]x07\[7\]](#)==0) && ([IDE\[1:0\]x07\[3\]](#)==0) for a port, the SATA device on that port is ready. BOZO: We should define bit 7 (BSY) & bit 3 (DRQ) in IDEx07 register definition.  
Else, loop until 30 s time-out; There is no SATA device attached if a time-out occurs.  
Note: Most drives don't need 30 s time-out. The 30 s time-out is only needed for some particularly large capacity SATA drives, which require a longer spin-up time during a cold boot.

### 2.15.3.3 SATA PHY Auto-Calibration Enablement

BIOS enables SATA PHY auto-calibration as follows:

1. Program [D11F0x88\[PIIVcoTune\]](#)=0011b.
2. Program [PMxDC\[PllCalibEn\]](#)=1.
3. Reset PHY:
  - A. Program [D11F0x84\[RSTB\]](#)=0 to assert reset.
  - B. Wait for 100 us.
  - C. Program [D11F0x84\[RSTB\]](#)=1 to release PHY reset.

### 2.15.3.4 SATA PHY Fine Tuning

The SBIOS should program the SATA controller in the sequence indicated below to fine tune the PHY. Performing this procedure provides sufficient time for the SATA controllers to correctly complete SATA drive

detection. The same procedure is required after the system resumes from the S3 state.

- Gen 3 settings:
  - Program `D11F0x80[15:0]=0130h` to select Gen 3 for all ports.
  - Program `D11F0x98[31:0]=0040f407h`.
- Gen 2 settings:
  - Program `D11F0x80[15:0]=0120h` to select Gen 2 for all ports.
  - Program `D11F0x98[31:0]=00403204h` to fine tune PHY for Gen 2.
- Gen 1 settings:
  - Program `D11F0x80[15:0]=0110h` to select Gen 1 for all ports.
  - Program `D11F0x98[31:0]=00403103h` to fine tune PHY for Gen 1.
- Squelch detector settings:
  - A. Program `PMxC8[EPromEFuseSelect]=1b` to select Efuse access.
  - B. Program `PMxD8[EpromEfuseIndex]=01h`.
  - C. Read from `PMxD9[4]` to get the setting of `APU_FCH_FUSE[12]`.
  - D. IF (`PMxD9[4]==0`) THEN
 

SATA RX squelch detection threshold is not fused, program the squelch detector threshold for all ports at all generation speed as follows:

    - Program `D11F0x80[15:0]=0130h`.
    - Program `D11F0x9C[RX_SQDET_TH]=101b`.
    - Program `D11F0x80[15:0]=0120h`.
    - Program `D11F0x9C[RX_SQDET_TH]=101b`.
    - Program `D11F0x80[15:0]=0110h`.
    - Program `D11F0x9C[RX_SQDET_TH]=101b`.

ELSE

    - a. Program `PMxD8[EpromEfuseIndex]=02h`.
    - b. Read from `PMxD9[2:0]` to get the fused setting for SATA port 1 squelch detector threshold.
    - c. Program the squelch detector threshold control register for port 1 at all generation speed:
      - Program `D11F0x80[15:0]=0031h`.
      - Program `D11F0x9C[RX_SQDET_TH]=PMxD9[2:0]`.
      - Program `D11F0x80[15:0]=0021h`.
      - Program `D11F0x9C[RX_SQDET_TH]=PMxD9[2:0]`.
      - Program `D11F0x80[15:0]=0011h`.
      - Program `D11F0x9C[RX_SQDET_TH]=PMxD9[2:0]`.
    - d. Program `PMxD8[EpromEfuseIndex]=01h`.
    - e. Read from `PMxD9[7:5]` to get the fused setting for SATA port 0 squelch detector threshold.
    - f. Program the squelch detector threshold control register for port 0 at all generation speed:
      - Program `D11F0x80[15:0]=0030h`.
      - Program `D11F0x9C[RX_SQDET_TH]=PMxD9[7:5]`.
      - Program `D11F0x80[15:0]=0020h`.
      - Program `D11F0x9C[RX_SQDET_TH]=PMxD9[7:5]`.
      - Program `D11F0x80[15:0]=0010h`.
      - Program `D11F0x9C[RX_SQDET_TH]=PMxD9[7:5]`.

ENDIF.

### 2.15.3.5 SATA PHY Reference Clock Selection

SATA PHY reference clock can originate from either internal or external clock. The following steps select SATA PHY reference clock source:

1. Select one of the following options for reference clock.

- Internal 48 MHz differential non-spread clock from pad (default):
    - a. Program [PMxDA\[RefClkSel\]](#)=1 to select reference clock from internal RDL.
    - b. Program [PMxDA\[RefDivSel\]](#)=0 to set PHY divider to div-by-1.
    - c. Program [D11F0x8C\[PLL\\_CLKF\]](#)=7Dh to set PLL feedback clock divider value to 6 GHz/48 MHz=7Dh.
  - External 25 MHz crystal non-spread clock from external clock chip (the clock path has to be routed on the board, in order for the setting to take effect):
    - a. Program [PMxDA\[RefClkSel\]](#)=0 to select reference clock from an external source, via the PAD\_XTALI and PAD\_XTALO, to SATA PHY.
    - b. Program [PMxDA\[RefDivSel\]](#)=0 to set PHY divider to div-by-1.
    - c. Program [D11F0x8C\[PLL\\_CLKF\]](#)=F0h to set PLL feedback clock divider value to 6 GHz/25 MHz=F0h.
2. Reset PHY:
- A. Program [D11F0x84\[RSTB\]](#)=0 to assert reset.
  - B. Wait for 100 us.
  - C. Program [D11F0x84\[RSTB\]](#)=1 to release PHY reset.

### 2.15.3.6 SATA Power Management

#### 2.15.3.6.1 SATA PHY Power Saving

The SATA PHY has different power saving states with the Active state consuming the most power. The table below summarizes the different controls during each power saving state.

#### 2.15.3.7 Enable Shadow Register Reload

When default PHY settings are not optimal, they need to be adjusted by software. Once these settings are re-programmed, software shall program [D11F0x84\[S5ShadowLdDis\]](#) to 0 to turn on shadow register reloading. When default PHY settings are optimal and need no adjustment, [D11F0x84\[S5ShadowLdDis\]](#) needs not to be altered and shadow register preloading is effectively disabled.

### 2.15.3.8 SATA Interrupt Handling

#### 2.15.3.8.1 Line Interrupt

The SATA interrupt mapping is specified by [IOC00 \[Pci\\_Intr\\_Index\]](#) and [IOC01 \[Pci\\_Intr\\_Data\]](#).

#### 2.15.3.8.2 MSI Message

SATA controller supports message-based interrupts. When MSI is enabled and the SATA controller owns N ports, as specified by [SATAx0C \[Ports Implemented \(PI\)\]](#), [D11F0x50\[MMC\]](#) should be programmed according to platform configurations:

- If [SATAx00\[CCCS\]](#)=1, [D11F0x50\[MMC\]](#) should be the minimum of 2M which satisfies  $2M \geq (N+1)$ . For example: if BIOS knows that system has 2 SATA ports in AHCI mode (N=2). If [SATAx00\[CCCS\]](#)=1, BIOS should program [D11F0x50\[MMC\]](#)=2 to request 4 MSI interrupts. If [SATAx00\[CCCS\]](#)=0, BIOS should program [D11F0x50\[MMC\]](#)=1 to request 2 MSI interrupts.

MSI capability pointer should be hidden when SATA subclass is configured in IDE mode (see [2.15.3.1 \[SATA Operating Mode\]](#)). To hide SATA MSI capability, the capability pointer offset needs to be re-programmed from its default setting to prevent the driver from enabling this feature.

### 2.15.3.9 Clear status of SATA PERR

BIOS should clear SATA PERR status soon after a cold boot, warm boot, any S3/S1 resume events, or an [IOCF9](#) initiated reset outside a warm boot before any SATA activity is initiated.

- Write 1 to clear [SMI<sub>x</sub>3C](#)[SataPerr].
- Write 1 to clear [SMI<sub>x</sub>84](#)[RasEvent55].

### 2.15.4 LPC Bus Interface

BIOS should program [D14F3xA0](#)[SpiBaseAddr] with non-zero address to enable the MMIO access to SPI ROM control registers.

#### 2.15.4.1 Enabling LPC DMA function

If DMA is required for the LPC interface, program the registers as the following:

- Program [D14F3x40](#)[LegacyDmaEnable]=1.
- Program [D14F3x78](#)[NoHog]=1.
- Program [PMx08](#)[ArbDmaDis]=1.
- Program [D14F3x78](#)[LDRQ1]=1 and [D14F3x78](#)[LDRQ0]=1.
- Program [PMx04](#)[LegacyDmaPrefetchEnhance]=1 for non-DOS mode. Note: This bit should only be enabled in the ACPI method (called by the OS). This ensures that it is enabled only when the system is in Windows<sup>®</sup> mode. Under DOS mode, this feature may not work properly and may cause the floppy to malfunction.

#### 2.15.4.2 Enabling SPI 100

To enable the support for SPI 100 MHz speed, software needs to program [SPIx20](#)[UseSpi100]=1. SPI 100 should be enabled on after the Auto ROM sizing has been completed (Auto ROM sizing is done by the software only during the initial boot when the system power state transitions from G3->S5->S0). The actual read speed also depends on the settings at [SPIx22](#) [[SPI100 Speed Config](#)].

### 2.15.5 SD Controller

The SD controller is SD 3.0 compliant host controller.

### 2.15.6 HD Audio

The FCH has one High Definition Audio controller (HD audio aka. Azalia), which can be enabled/disabled by programming [PMxEB](#)[AzEnable].

The HD audio controller supports up to 4 codecs with one AZ\_SDIN pin from each codec. The four AZ\_SDIN pins are multiplexed with GPIO167-170 (GPIOxA7-GPIOxAA). If a particular pin is to be used for HD audio functionality and the integrated pull-down is to be used rather than external pull-down resistor, in addition to being configured for HD audio, the following bits need to be set:

- GPIOxA7=3Eh
- GPIOxA8=3Eh
- GPIOxA9=3Eh
- GPIOxAA=3Eh

For example, if only GPIO167 and GPIO168 are to be used for HD audio, then only GPIOxA7 and GPIOxA8 need to be programmed to 3Eh. See [3.26.12](#) [[GPIO Pin control registers](#)].

### 2.15.6.1 HD Audio AF and MSI Capability

The Advanced Feature (AF) capability and MSI capability in HD audio controller are controlled by [D14F2x44\[EnAFCap\]](#) and [D14F2x44\[EnMsiCap\]](#) respectively. The settings of these two bits affect how the AF capability and MSI capability are linked to the capability pointer linked list.

**Table 81: HD Audio AF and MSI Capability Settings**

| <a href="#">D14F2x44</a><br>[EnAFCap] | <a href="#">D14F2x44</a><br>[EnMsiCap] | <a href="#">D14F2x50</a><br>[NextPtr] | <a href="#">D14F2x60</a><br>[CapID] | <a href="#">D14F2x60</a><br>[NextPtr] | <a href="#">D14F2x70</a><br>[AFC-apID] | <a href="#">D14F2x70</a><br>[NextPtr] | <a href="#">D14F2x70</a><br>[AFLengt<br>h] | <a href="#">D14F2x70</a><br>[25:24] |
|---------------------------------------|----------------------------------------|---------------------------------------|-------------------------------------|---------------------------------------|----------------------------------------|---------------------------------------|--------------------------------------------|-------------------------------------|
| 0                                     | 0                                      | 0h                                    | 0h                                  | 0h                                    | 0h                                     | 0h                                    | 0h                                         | 0h                                  |
| 0                                     | 1                                      | 60h                                   | 5h                                  | 0h                                    | 0h                                     | 0h                                    | 0h                                         | 0h                                  |
| 1                                     | 0                                      | 70h                                   | 0h                                  | 0h                                    | 13h                                    | 0h                                    | 6h                                         | 3h                                  |
| 1                                     | 1                                      | 60h                                   | 5h                                  | 70h                                   | 13h                                    | 0h                                    | 6h                                         | 3h                                  |

### 2.15.7 ASF Controller

The ASF controller can be used in a slave mode to support DASH clients. When the platform is configured for DASH the BIOS should at the minimum set the following registers to ensure the ASF is configured in slave mode and the control commands are defined properly in the ASF tables.

- When operating in Master mode, BIOS should program [PMx28\[AsfSmMasterEn\]](#)=1. BIOS should program [PMx28\[AsfSmMasterEn\]](#) back to 0 after the master operations are done.
- When operating in Slave mode, BIOS should program [PMx28\[AsfSmMasterEn\]](#)=0.

In addition to support remote DASH operations, BIOS should ensure that the ASF tables define the correct command codes and [ASFx0E \[RemoteCtrlAdr\]](#) has to be programmed with the same value reported in the ASF control data table.

ASF controller can behave like remote control device to accept the command from client side to do the reset/power down/power up/power cycle. BIOS reports those in ASF control data table. The command and command data are defined in [Table 82](#).

**Table 82: ASF Remote Control Commands**

| Remote Control | Control Command | Control data |
|----------------|-----------------|--------------|
| Reset          | 50h             | 00h          |
| Power Up       | 51h             | 00h          |
| Power Down     | 52h             | 00h          |
| Power Cycle    | 53h             | 00h          |

### 2.15.8 Integrated Micro-Controller

The FCH supports an integrated micro-controller (IMC) to run the keyboard BIOS and/or other algorithms. The IMC is an enhanced 8051 with a RISC-like architecture which allows it to perform most instructions in 1-4 clocks (instead of 12 clocks in the original 8051).

The IMC can also be enabled by programming [PMxD6\[ImcEnable\]](#).

### 2.15.9 On-Chip Clock Generator

There are two clocking modes in which this chip can be brought up based on the boot strap pin LPCCLK1. SBIOS should read [MISCx80\[ClkGenStrap\]](#) to determine clock generator mode. SBIOS should program

**MISCx40**[OscClkSwitchEn] to 1 to select average 14 MHz OSC clock provided by internal PLL in both internal and external clocking mode.

### 2.15.9.1 Power Saving In Internal Clock Mode

GPP\_CLK\_P/N pins are powered off when this chip is strapped to use an external clock, and powered on when strapped to operate in internal clock mode. The GPP\_CLK clocks are mapped to corresponding CLK\_REQ# pins. The GPP\_CLK0/1/2/3 mapping is defined at **MISCx00**[15:0]. SLT\_GFX\_CLK mapping is defined at **MISCx04**[7:4]. In internal clock mode, a selected GPP\_CLK can be powered off when the corresponding CLK\_REQ# is asserted. See **MISCx00** & **MISCx04** for details.

Software can also program **MISCx04**[PCIE\_RCLK\_PowerDownEnable]=1 to turn off 100 MHz reference clock input buffer in internal clock generator mode for power saving.

### 2.15.9.2 Global A-Link / B-Link Clock Gating

Software needs to program **MISCx2C**[AlinkClkGateOffEn]=1 and **PMx04**[ABLinkClkGateEn]=1 to enable global A-link clock gate off function.

Software needs to program **MISCx2C**[BlinkClkGateOffEn]=1 and **PMx04**[ABLinkClkGateEn]=1 to enable global B-link clock gate off function.

**PMx04**[ABLinkClkGateEn] is a non-sticky bit and needs to be programmed to 1 after PCI reset and S3/S4/S5 state, if global A-link / B-link gating function has been enabled. **MISCx2C**[AlinkClkGateOffEn] and **MISCx2C**[BlinkClkGateOffEn] are sticky bits.

### 2.15.9.3 CG\_PLL CMOS Clock Driver Setting for Power Saving

Software programs the following registers to select CMOS clock driver for CG1\_PLL in internal & external clock mode for power saving:

- A. Program **MISCx1C**[CgpllClkDriverUpdate]=0.
- B. Program **MISCx1C**[Cg1ClkDriverType]=1011b and Program **MISCx1C**[Cg1RefClk48MHzDriverType]=0010b.
- C. Perform a software reset through **IOCF9**.

These settings will only need to be applied once when the chip is booting up from G3-S5->S0. There is no need to do this for every reset since the setting is sticky.

### 2.15.10 Scallion Gasket

The Scallion gasket (SBG) is responsible for converting between the protocols used by the Scallion interface and the A-link bridge interface. BIOS should program **PMxE0** to set up base address before accessing AB configuration registers.

### 2.15.11 A-Link Bridge

The A-link bridge (AB) sits behind the Scallion gasket and acts as the bridge between Scallion and A-link/B-link bus.

#### 2.15.11.1 Detection of Upstream Interrupts

BIOS should enable AB to detect upstream interrupts for the purpose of system management.

- Program **ABx04\_x94**[MsiAddr[39:20]] with CPU interrupt delivery address [39:20].
- Program **ABx04\_x94**[MsiAddrEn]=1.

### 2.15.11.2 AB Memory Power Saving

The following sequence enables AB memory power saving:

- A. Program [MISCx68](#)[ABBypassMemDsd]=0 to enable AB memory DSD.
- B. Program [ABx04\\_x58](#)[BIMemSDEn]=1 to enable B-link memory shutdown.
- C. Program [ABx04\\_x58](#)[AImemSDEn]=1 to enable A-link memory shutdown.

### 2.15.11.3 AB Internal Clock Gating

The following sequence enables AB internal clock gating:

- A. Program [ABx04\\_x54](#)[BIClkGateDelay]=10h to set the number of cycles to delay before gating B-link clocks.
- B. Program [ABx04\\_x10054](#)[AIClkGateDelay]=10h to set the number of cycles to delay before gating A-link clocks.
- C. Program [ABx04\\_x54](#)[BIClkGateEn]=1 to enable medium grain B-link clock gating.
- D. Program [ABx04\\_x54](#)[DbgClkGateEn]=1 to disable debug only B-link clocks.
- E. Program [ABx04\\_x10054](#)[AIClkGateEn]=1 to enable medium grain A-link clock gating.
- F. Program [ABx04\\_x10054](#)[DbgClkGateEn]=1 to disable debug only A-link clocks.

### 2.15.11.4 AB 32/64 Byte DMA Write Enable

To enable AB 32 byte/64 byte DMA write, software needs to program [ABx04\\_x54](#)[UpWr16BMode]=0 and [ABx04\\_x54](#)[UpSWrByteCntSbgMode]=1 to disable 16 byte write splitting and enable SBG mode byte-count calculation logic. Software should also make sure [ABx04\\_x204](#)[Dma16ByteMode]=0.

### 3 Registers

This section provides detailed field definitions for the core register sets in the processor.

#### 3.1 Register Descriptions and Mnemonics

Each register in this document is referenced with a mnemonic. Each mnemonic is a concatenation of the register-space indicator and the offset of the register. Here are the mnemonics for the various register spaces:

- **IOXXX**: x86-defined input and output address space registers; XXX specifies the hexadecimal byte address of the IO instruction. This space includes IO-space configuration access registers, [IOCF8 \[IO-Space Configuration Address\]](#) and [IOCFC \[IO-Space Configuration Data Port\]](#), the GPU VGA registers, and the legacy block configuration registers. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.2 \[IO Space Registers\]](#) and [3.26.1 \[Legacy Block Configuration Registers \(IO\)\]](#).
- **APICXX0**: APIC memory-mapped registers; XX0 is the hexadecimal byte address offset from the base address. See [2.4.8.1.2 \[APIC Register Space\]](#).
- **CPUID FnXXXX\_XXXX\_EiX[\_xYYY]**: processor capabilities information returned by the CPUID instruction. See [3.18 \[CPUID Instruction Registers\]](#). Each core may only access this information for itself.
- **MSRXXXX\_XXXX**: [MSRs](#); XXXX\_XXXX is the hexadecimal MSR number. This space is accessed through x86-defined RDMSR and WRMSR instructions. Unless otherwise specified there is one set of these registers [Per-core](#). See [2.4.1 \[L2 complex\]](#).
- **DXFYxZZZ**: PCI-defined configuration space; X specifies the hexadecimal device number (this may be 1 or 2 digits), Y specifies the function number, and ZZZ specifies the hexadecimal byte address (this may be 2 or 3 digits); e.g., D18F3x40 specifies the register at device 18h, function 3, and address 40h. See [2.7 \[Configuration Space\]](#), for details about configuration space.
  - Some register in D18F2xXXX have the `_dct[0]` mnemonic suffix. See [2.9.3 \[DCT Configuration Registers\]](#).
- **PMCxXXX**: core performance monitor events; XXX is the hexadecimal event counter number programmed into [MSRC001\\_00\[03:00\]\[EventSelect\]](#); See [2.6.1.1 \[Core Performance Monitor Counters\]](#).
  - When PMCxXXX is followed by [z:y] then UnitMask[z:y] is being specified.
- **L2IPMCxXXX**: L2 performance monitor events; XXX is the hexadecimal event counter number programmed into [MSRC001\\_023\[6,4,2,0\]\[EventSelect\]](#); See [2.6.1.2 \[L2I Performance Monitor Counters\]](#).
  - When PMCxXXX is followed by [z:y] then UnitMask[z:y] is being specified.
- **NBPMCxXXX**: NB performance monitor events; XXX is the hexadecimal event counter number programmed into [MSRC001\\_024\[6,4,2,0\]\[EventSelect\]](#); See [2.6.1.3 \[NB Performance Monitor Counters\]](#).
  - When NBPMCxXXX is followed by [z:y] then UnitMask[z:y] is being specified.
- **ABxXX**: ALink Bridge registers; XX specifies the hexadecimal byte address offset from the base address. The base address for this space is specified by [PMxE0 \[ABRegBar\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.2 \[AB Configuration Registers \(Scallion\)\]](#).
- **IDE[Y]xXX**: SATA controller IDE mode IO mapped registers; XX specifies the hexadecimal byte address offset from the base address; Y specifies primary drive (0) or secondary drive (1). The base address for this space is specified in [Table 231 \[IDE Compatibility Mode and Native Mode Address Mapping\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.3.2.1 \[IDE Compatibility Mode and Native Mode \(BAR0, BAR1, BAR2, BAR3\) Registers\]](#).
- **IDE\_BMxXX**: SATA controller IDE mode IO mapped bus master registers; XX specifies the hexadecimal byte address offset from the base address. The base address for this space is specified by [D11F0x20 \[Bus Master Interface Register Base Address \(BAR4\)\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.3.2.2 \[IDE Bus Master \(BAR4\) Registers\]](#).

- **SATAxXXX**: SATA controller AHCI mode memory mapped registers; XXX specifies the hexadecimal byte address offset from the base address. The base address for this space is specified by [D11F0x24 \[AHCI Base Address \(BAR5\)\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.3.3 \[SATA Memory Mapped AHCI Registers\]](#).
- **SATA\_EMxXX**: SATA controller AHCI mode memory mapped enclosure buffer management registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.3.3.3 \[Enclosure Buffer Management Registers\]](#).
- **OHCI[Y]xXXX**: USB OHCI controller memory mapped registers; XXX specifies the hexadecimal byte address offset from the base address; Y specifies the OHCI controller number; e.g., OHCI[1]x04 specifies OHCI controller 1 memory mapped control register offset 04. The base address for this space is specified by [D\[16,13,12\]F0x10 \[OHCI Base Address\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.4.1.2 \[OHCI Memory Mapped IO Registers\]](#).
- **EHCI[Y]xXX**: USB EHCI controller memory mapped registers; XX specifies the hexadecimal byte address offset from the base address; Y specifies the EHCI controller number; e.g., EHCI[1]x04 specifies EHCI controller 1 memory mapped control register offset 04. The base address for this space is specified by [D\[16,13,12\]F2x10 \[BAR\\_EHCI\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.4.2.2 \[EHCI Memory Mapped IO Registers\]](#).
- **xHCI\_PMxXX**: USB xHCI controller ACPI memory mapped registers; XX specifies the hexadecimal byte address offset from the base address. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.4.3.2 \[xHCI Power Management Registers\]](#).
- **SDHCxXX**: Secure Digital host controller memory mapped registers; XX specifies the hexadecimal byte address offset from the base address. The base address for this space is specified by [D14F7x14 \[Upper Base Address Reg 0\]](#), [D14F7x10 \[Base Address Reg 0\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.6.2 \[SD Host Controller Configuration Registers \(SDHC\)\]](#).
- **ASFxXX**: ASF registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.7.2 \[ASF \(Alert Standard Format\) Registers\]](#).
- **SMBUSxXX**: SMBus registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.7.3 \[SMBus Registers\]](#).
- **IOAPICxXX**: IOAPIC registers; XX specifies the hexadecimal byte address offset from the base address. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.8 \[IOAPIC Registers\]](#).
- **SPIxXX**: SPI memory mapped registers; XX specifies the hexadecimal byte address offset from the base address. The base address is specified by [D14F3xA0 \[SPI Base\\_Addr\]](#). Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.9.2 \[SPI Registers\]](#).
- **HPETxXXX**: HPET registers; XXX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.10 \[High Precision Event Timer \(HPET\) Registers\]](#).
- **MISCxXX**: ACPI miscellaneous control registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.11 \[Miscellaneous \(MISC\) Registers\]](#).
- **GPIOxXX**: GPIO registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.12.1 \[GPIO Registers\]](#).

- **IOMUXxXX**: IOMux registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.12.2 \[IOMux Registers\]](#).
- **PMxXX**: power management registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.13 \[Power Management \(PM\) Registers\]](#).
- **PM2xXX**: power management block 2 registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.14 \[Power Management Block 2 \(PM2\) Registers\]](#).
- **SMIxXX**: SMI registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.16 \[SMI Registers\]](#).
- **WDTxXX**: Watchdog timer registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.17 \[Watchdog Timer \(WDT\) Registers\]](#).
- **AcDcTimerxXX**: AC/DC wake alarm timer registers; XX specifies the hexadecimal byte address offset. Unless otherwise specified, there is one set of these registers per node; the registers in a node are accessible to any core on that node. See [3.26.18 \[Wake Alarm Device \(AcDcTimer\) Registers\]](#).

Each mnemonic may specify the location of one or more registers that share the same base definition. A mnemonic that specifies more than one register will contain one or more ranges within braces. The ranges are specified as follows:

- Comma separated lists [A,B]: Define specific instances of a register, e.g., D0F3x[1,0]40 defines two registers D0F3x40 and D0F3x140.
- Colon separated ranges [A:B]: Defines all registers that contain the range between A and B. Examples:
  - D0F3x[50:40] defines five registers D0F3x40, D0F3x44, D0F3x48, D0F3x4C, and D0F3x50.
  - D[8:2]F0x40 defines seven registers D2F0x40, D3F0x40, D4F0x40, D5F0x40, D6F0x40, D7F0x40, and D8F0x40.
  - D0F0xE4\_x013[2:0]\_0000 defines three registers D0F0xE4\_x0130\_0000, D0F0xE4\_x0131\_0000, and D0F0xE4\_x0132\_0000.
- Colon separated ranges with an explicit step [A:BstepC]: Defines the registers from A to B, C defines the offset between registers., e.g., D0F3x[50:40:step8] defines three registers D0F3x40, D0F3x48, and D0F3x50.

The processor includes a single set of IO-space and configuration-space registers. However, APIC, CPUID, and MSR register spaces are implemented once per processor core. Access to IO-space and configuration space registers may require software-level techniques to ensure that no more than one core attempts to access a register at a time.

The following is terminology found in the register descriptions.

**Table 83: Terminology in Register Descriptions**

| Term         | Definition                                                                                                                                                                                                                                                                |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BIOS</b>  | Software recommendation syntax. See <a href="#">3.1.2 [Software Recommendation (BIOS, SBIOS, IBIOS)]</a> .                                                                                                                                                                |
| <b>SBIOS</b> |                                                                                                                                                                                                                                                                           |
| <b>See</b>   | Reference to remote definition. See <a href="#">3.1.3 [See Keyword (See:)]</a> .                                                                                                                                                                                          |
| <b>Alias</b> | <p>The alias keyword allows the definition of a soft link between two registers.</p> <ul style="list-style-type: none"> <li>• X is an alias of Y: X is a soft link to the register Y.</li> <li>• X1, X2 are an alias of Y: Both X1 and X2 are soft links to Y.</li> </ul> |

**Table 83: Terminology in Register Descriptions**

| Term                | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IF                  | Allows conditional definition as a function of register fields. The syntax is: <ul style="list-style-type: none"><li>• IF (conditional-expression) THEN definition ENDIF.</li><li>• IF (conditional-expression) THEN definition ELSE definition ENDIF.</li><li>• IF (conditional-expression) THEN definition ELSEIF (conditional-expression) THEN definition ELSE definition ENDIF.</li></ul>                                                                               |
| THEN                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ELSEIF              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ELSE                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ENDIF               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Access Types        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Read                | Capable of being read by software.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Read-only           | Capable of being read but not written by software.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Write               | Capable of being written by software.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Write-only          | Write-only. Capable of being written by software. Reads are undefined.                                                                                                                                                                                                                                                                                                                                                                                                      |
| Read-write          | Capable of being written by software and read by software.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Set-by-hardware     | Register field is set high by hardware, set low by hardware, or updated by hardware.                                                                                                                                                                                                                                                                                                                                                                                        |
| Cleared-by-hardware |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Updated-by-hardware |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Updated-by-SMU      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Write-1-to-clear    | Software must write a 1 to the bit in order to clear it. Writing a 0 to these bits has no affect.                                                                                                                                                                                                                                                                                                                                                                           |
| Write-1-only        | Software can set the bit high by writing a 1 to it. Writes of 0 have no effect.                                                                                                                                                                                                                                                                                                                                                                                             |
| Reset-applied       | Takes effect on warm reset.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| GP-read             | GP exception occurs on read.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| GP-write            | GP exception occurs on write.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| GP-read-write       | GP exception occurs on a read or a write.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Per-core            | One instance per core. Only valid for MMIO config space. Writes of these bits from one core only affect that core’s register. Reads return the values appropriate to that core.                                                                                                                                                                                                                                                                                             |
| Per-compute-unit    | One instance per compute unit. Writes of these bits from one core only affect that compute unit’s register. Reads return the values appropriate to that compute unit. See <a href="#">2.4.2.1 [Registers Shared by Cores in a L2 complex]</a> .                                                                                                                                                                                                                             |
| Per-L2              | One instance per L2 cache. See <a href="#">CPUID Fn8000_001D_EAX_x2[NumSharingCache]</a> .                                                                                                                                                                                                                                                                                                                                                                                  |
| Per-node            | One instance per node. Only valid for MSR space. See <a href="#">3.1.1 [Northbridge MSRs In Multi-Core Products]</a> .                                                                                                                                                                                                                                                                                                                                                      |
| Not-same-for-all    | Provide indication as to whether all instances of a given register should be the same across all cores/nodes according to the following equation:<br>SameOnAllCheckEnabled = (Writable && (same-for-all   MSR) && ~(not-same-for-all    UpdatedByHw)). UpdatedByHw = (Updated-by-hardware    set-by-hardware    cleared-by-hardware    set-when-done    cleared-when-done). MSR’s should not be marked with <a href="#">Same-for-all</a> because it is the default setting. |
| Same-for-all        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Field Definitions   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table 83: Terminology in Register Descriptions**

| Term              | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Reserved</b>   | Field is reserved for future use. Software is required to preserve the state read from these bits when writing to the register. Software may not depend on the state of reserved fields nor on the ability of such fields to return the state previously written. Reset must be specified if the reset value is not 0. Reset may be omitted if the reset value is 0. Read-write, if it exists, must be in internal-only text. Read-only is implied if Read-write is not specified. |
| <b>Unused</b>     | Field is reserved for future use. Software is not required to preserve the state read from these bits when writing to the register. Software may not depend on the state of unused fields nor on the ability of such fields to return the state previously written.                                                                                                                                                                                                                |
| <b>MBZ</b>        | Must be zero. If software attempts to set an MBZ bit to 1, a general-protection exception (#GP) occurs.                                                                                                                                                                                                                                                                                                                                                                            |
| <b>RAZ</b>        | Read as zero. Writes are ignored, unless RAZ is combined with write-only or write-1-only. Reset may be omitted.                                                                                                                                                                                                                                                                                                                                                                    |
| Reset Definitions |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Reset</b>      | The reset value of each register is provided below the mnemonic or in the field description. Unless otherwise noted, the register state matches the reset value when RESET_L is asserted (either a cold or a warm reset). Reset values may include: <ul style="list-style-type: none"> <li>• <b>X</b>: an X in the reset value indicates that the field resets (warm or cold) to an unspecified state.</li> </ul>                                                                  |
| <b>Cold reset</b> | The field state is not affected by a warm reset (even if the field is labeled “cold reset: X”); it is placed into the reset state when PWROK is deasserted. See "Reset" above for the definition of characters that may be found in the cold reset value.                                                                                                                                                                                                                          |
| <b>Value</b>      | The current value of a read-only field or register. A value statement explicitly defines the field or register as read-only and the value returned under all conditions including after reset events. A field labeled “Value:” will not have a separate reset definition.                                                                                                                                                                                                          |

### 3.1.1 Northbridge MSRs In Multi-Core Products

MSRs that control Northbridge functions are shared between all cores on the node in a multi-core processor (e.g. [MSRC001\\_001F](#)). If control of Northbridge functions is shared between software on all cores, software must ensure that only one core at a time is allowed to access the shared MSR. Some MSR's are conditionally shared; see [D18F3x44](#)[NbMcaToMstCpuEn].

### 3.1.2 Software Recommendation (BIOS, SBIOS, IBIOS)

The following keywords specify the recommended value to be set by software.

- BIOS: AMD BIOS.
- SBIOS: Platform BIOS.

Syntax: BIOS: integer-expression. Any of the supported tags can be substituted for BIOS.

If “BIOS:” occurs in a register field then the recommended value is applied to the field. If “BIOS:” occurs after a register name but outside of a register field table row then the recommended value is applied to the width of the register.

### 3.1.3 See Keyword (See:)

There is a special meaning applied to the use of “See:” that differs from the use of See not followed by a “:”.

- See, not followed by a “:”, simply refers the reader to a document location that contains related information.
- See followed by a “:” is a shorthand notation that indicates that the definition for this register or register field inherits all properties and definitions from the register or register field that follows "See:". Any definition local to the register or register field supercedes this inheritance.

“See:” can be used in the following ways:

- Full register width. [CPUID Fn0000\\_0001\\_EAX](#) inherits it’s full register width definition from [D18F3xFC](#).
- Register field. [MSR0000\\_0277\[PA1MemType\]](#) inherits it’s definition from PA0MemType, however, the local reset of 4h overrides the inherited PA0MemType reset of 6h.
- Valid values definition. [MSR0000\\_020\[E,C,A,8,6,4,2,0\]\[MemType\]](#), for example, inherits the valid values definition from [Table 191 \[Valid Values for Memory Type Definition\]](#).

### 3.1.4 Mapping Tables

The following mapping table types are defined.

#### 3.1.4.1 Register Mapping

The register mapping table specifies the specific function for each register in a range of registers.

[Table 176](#), for example, specifies that the D18F5x160 function is for NB P-state 0.

#### 3.1.4.2 Index Mapping

The index mapping table is similar to the register mapping table, but specifies the register by index instead of by full register mnemonic.

[Table 135 \[Index Mapping for D18F2x9C\\_x0D0F\\_0\[F,8:0\]02\\_dct\[0\]\]](#), for example, specifies that the [D18F2x98\\_dct\[0\]\[31:0\]==0D0F\\_0002h](#), or [D18F2x9C\\_x0D0F\\_0002\\_dct\[0\]](#), function is for Byte 0.

#### 3.1.4.3 Field Mapping

The field mapping table maps the fields of a range of registers. The rows are the registers that are mapped. Each column specifies a field bit range that is mapped by that column for all registers. The cell at the intersection of the register and the field bit range specifies the suffix that is appended to the register field. “Reserved” specifies that the field is reserved for the register of that row. “-” indicates no specification and the table cell should be skipped.

#### 3.1.4.4 Broadcast Mapping

The broadcast mapping table maps a register address to a range of register addresses that are read or written as a group when the broadcast register address is read or written. The register address is formed by the concatenation of the row address with the column address. The cell at the intersection of the row and column address is a range of register addresses that will be read or written as a group when the row and column address is read or written.

### 3.1.4.5 Reset Mapping

The reset mapping table specifies the reset, cold reset, or value for each register in a range of registers.

Table 186 [Reset Mapping for CPUID Fn8000\_0000\_E[D,C,B]X], for example, specifies that the CPUID Fn0000\_0000\_EBX register has a value of 6874\_7541h, with a comment of “The ASCII characters “h t u A””.

### 3.1.4.6 Valid Values

The valid values table defines the valid values for one or more register fields. The valid values table is equivalent in function to the Bits/Description tables in register fields (E.g. MSR0000\_0277[PA0MemType]) and is most often used when the table becomes too large and unwieldy to be included into the register field. (E.g. Table 191 [Valid Values for Memory Type Definition])

### 3.1.4.7 BIOS Recommendations

The BIOS recommendations table defines “BIOS:” recommendations that are conditional and complex enough to warrant a table.

Table 164 [BIOS Recommendations for D18F2x1B[4:0]], for example, specifies the BIOS recommendations for D18F2x1B0[DcqBwThrotWm] and D18F2x1B4[DcqBwThrotWm1, DcqBwThrotWm2]. All cells under the “Condition” header for a given row are ANDed to form the condition for the values to the right of the condition. For example, rows 1-3 and column 1 provide the following equivalent BIOS recommendation:

- D18F2x1B0[DcqBwThrotWm]: BIOS: IF (DdrRate==667) THEN 4h ELSEIF (DdrRate==800) THEN 5h ELSEIF (DdrRate==1066) THEN 6h ELSEIF etc.

## 3.2 IO Space Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention.

### IOCF8 IO-Space Configuration Address

Reset: 0. IOCF8 [IO-Space Configuration Address], and IOCFC [IO-Space Configuration Data Port], are used to access system configuration space, as defined by the PCI specification. IOCF8 provides the address register and IOCFC provides the data port. Software sets up the configuration address by writing to IOCF8. Then, when an access is made to IOCFC, the processor generates the corresponding configuration access to the address specified in IOCF8. See 2.7 [Configuration Space].

IOCF8 may only be accessed through aligned, DW IO reads and writes; otherwise, the accesses are passed to the appropriate IO link. Accesses to IOCF8 and IOCFC received from an IO link are treated as all other IO transactions received from an IO link and are forwarded based on the settings in D18F1x[DC:C0] [IO-Space Base/Limit]. IOCF8 and IOCFC in the processor are not accessible from an IO link.

| Bits  | Description                                                                                                                                                                                                                                                                                                   |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>ConfigEn: configuration space enable.</b> Read-write. 1=IO read and write accesses to IOCFC are translated into configuration cycles at the configuration address specified by this register. 0=IO read and write accesses are passed to the appropriate IO link and no configuration access is generated. |
| 30:28 | Reserved.                                                                                                                                                                                                                                                                                                     |
| 27:24 | <b>ExtRegNo: extended register number.</b> Read-write. ExtRegNo provides bits[11:8] and RegNo provides bits[7:2] of the byte address of the configuration register. ExtRegNo is reserved unless it is enabled by MSRC001_001F[EnableCf8ExtCfg].                                                               |

|       |                                                                                                |
|-------|------------------------------------------------------------------------------------------------|
| 23:16 | <b>BusNo: bus number.</b> Read-write. Specifies the bus number of the configuration cycle.     |
| 15:11 | <b>Device: bus number.</b> Read-write. Specifies the device number of the configuration cycle. |
| 10:8  | <b>Function.</b> Read-write. Specifies the function number of the configuration cycle.         |
| 7:2   | <b>RegNo: register address.</b> Read-write. See <a href="#">IOCF8</a> [ExtRegNo].              |
| 1:0   | Reserved.                                                                                      |

### IOCF8 IO-Space Configuration Data Port

---

| Bits | Description                                                    |
|------|----------------------------------------------------------------|
| 31:0 | <b>Data.</b> Read-write. Reset: 0. See <a href="#">IOCF8</a> . |

### 3.3 Device 0 Function 0 (Root Complex) Configuration Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space.

#### D0F0x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID: device ID.</b> Read-only. Value: 1536h. |
| 15:0  | <b>VendorID: vendor ID.</b> Read-only. Value: 1022h. |

#### D0F0x04 Status/Command

Reset: 0000\_0004h.

| Bits  | Description                                                              |
|-------|--------------------------------------------------------------------------|
| 31:21 | Reserved.                                                                |
| 20    | <b>CapList: capability list.</b> Read-only. 1=Capability list supported. |
| 19:3  | Reserved.                                                                |
| 2     | <b>BusMasterEn: bus master enable.</b> Read-only.                        |
| 1     | <b>MemAccessEn: memory access enable.</b> Read-only.                     |
| 0     | <b>IoAccessEn: IO access enable.</b> Read-only.                          |

#### D0F0x08 Class Code/Revision ID

Reset: 0600\_0000h.

| Bits | Description                                                                                                       |
|------|-------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode: class code.</b> Read-only. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID: revision ID.</b> Read-only.                                                                             |

#### D0F0x0C Header Type

Reset: 0080\_0000h.

| Bits  | Description                                                                        |
|-------|------------------------------------------------------------------------------------|
| 31:24 | Reserved.                                                                          |

Software can only utilize device and function number combinations that are used by other (local) PCIe bridges. This effectively allows swapping of device and function numbers between bridges.

### D0F0xB8 SMU Index Address

The index/data pair registers, **D0F0xB8** and **D0F0xBC**, are used to access the registers at **D0F0xBC\_x[FFFFFFFF:00000000]**. To access any of these registers, the address is first written into the index register, **D0F0xB8**, and then the data is read from or written to the data register, **D0F0xBC**. Only a subset of SMU registers are listed in the BKDG.

### D0F0xBC\_x3FD[9C:10:step14] LCLK DPM Activity Thresholds

Reset: xxxx\_xxxxh. See 2.5.6.1.3 [LCLK DPM]. Each register in D0F0xBC\_x3FD[9C:10:step14] corresponds to one LCLK DPM state as follows.

Table 87: Register Mapping for D0F0xBC\_x3FD[9C:10:step14]

### D0F0xC8 DEV Index Address

The index/data pair registers, [D0F0xC8](#) and [D0F0xCC](#) are used to access the registers at [D0F0xCC\\_x\[FF:00\]](#). To access any of these registers, the address is first written into the index register, [D0F0xC8](#), and then the data is read from or written to the data register, [D0F0xCC](#). Specific bridges (Device/Function) are selected using the [D0F0xC8\[NbDevIndSel\]](#) field.

**D0F0xE0 Link Index Address 1**

Reset: 0130\_8001h.

[D0F0xE0](#) and [D0F0xE4](#) are used to access [D0F0xE4\\_x\[FFFF\\_FFFF:0000\\_0000\]](#). To read or write to one of these register, the address is written first into the address register [D0F0xE0](#) and then the data is read from or written to the data register [D0F0xE4](#).

The phy index registers ([D0F0xE4\\_x0\[2:1\]xxx\\_xxxx](#)) mapping to a specific phy, pin or pin group is shown in a table in the register definition. For example, to perform a read or write operation to configure Gfx phy 0 (P\_GFX\_[T,R]X[P,N][7:0] pin group) compensation, software should program [D0F0xE0\[31:0\]=0120\\_0000h](#). Accessing any register number that is not listed in the mapping table may result in undefined behavior.

Some phy registers support broadcast write operations to groups of 4 or 8 lanes. For example, to perform broadcast write operation to configure Gfx Link[3:0] (P\_GFX\_RX[P,N][3:0] lanes) receiver phase loop filter, software should program [D0F0xE0\[31:0\]=0120\\_5602h](#).

| 11   | <b>ConfigXferMode</b> . Read-write. 1=PCIe core strap settings take effect immediately. 0=PCIe core strap settings take effect when the PCIe core is reset.                                      |
| 10   | <b>BlockOnIdle</b> . Read-write. 1=The PCIe core must be idle before hardware initiates a reconfiguration. 0=The PCIe core does not have to be idle before hardware initiates a reconfiguration. |
| 4:2  | <b>ResetPeriod</b> . Read-write. BIOS:2h. Specifies the amount of time that resets are asserted during an atomic reset or reconfiguration. 5h-7h: Reserved. Bozo: Need encoding.                 |
| 0    | <b>ReconfigureEn</b> . Read-write. 1=Atomic reconfiguration enabled.                                                                                                                             |

**D0F0xE4\_x0130\_80F0 BIOS Timer**

Reset: 0000\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                    |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>MicroSeconds</b> . Read-write; Updated-by-hardware; real-time-update. This field increments once every microsecond when the timer is enabled. The counter rolls over and continues counting when it reaches its FFFF_FFFFh. A write to this register causes the counter to reset and begin counting from the value written. |

**D0F0xE4\_x0130\_80F1 BIOS Timer Control**

### 3.4 Device 0 Function 2 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space]. See 2.11.6 [PCIe Client Interface Control].

#### D0F2xF8 PCIe Client Interface Index

The index/data pair registers, [D0F2xF8](#) and [D0F2xFC](#) are used to access the registers at [D0F2xFC\\_x\[FFFF:0000\]\\_L1i\[3:0\]](#). To access any of these registers, the address is first written into the index register, [D0F2xF8](#), and then the data is read from or written to the data register, [D0F2xFC](#).

Registers in the L1 indexed space have one instance per L1 denoted by [\\_L1i\[x\]](#) where  $x = \text{D0F2xF8}[\text{L1cfgSel}]$ . The syntax for this register type is described by example as follows:

- [D0F2xFC\\_x32](#) refers to all instances of the [D0F2xFC\\_x32\\_L1i](#) registers.
- [D0F2xFC\\_x32\\_L1i\\_L1i\[1\]](#) refers to the [D0F2xFC\\_x32](#) register instance for the BIF L1.

| Bits  | Description                                                                                                                                                                                                                                                                                                          |      |             |    |        |    |        |    |           |       |          |

|---|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 5 | <b>PalSnoopEn: VGA palette snoop enable.</b> Read-only.                                                                                           |
| 4 | <b>MemWriteInvalidateEn: memory write and invalidate enable.</b> Read-only.                                                                       |
| 3 | <b>SpecialCycleEn: special cycle enable.</b> Read-only.                                                                                           |
| 2 | <b>BusMasterEn: bus master enable.</b> Read-write. 1=Memory and IO read and write request generation enabled.                                     |
| 1 | <b>MemAccessEn: IO access enable.</b> Read-write. This bit controls if memory accesses targeting this device are accepted. 1=Enabled. 0=Disabled. |
| 0 | <b>IoAccessEn: IO access enable.</b> Read-write. This bit controls if IO accesses targeting this device are accepted. 1=Enabled. 0=Disabled.      |

### D1F1x08 Class Code/Revision ID

Reset: 0403\_0000h.

| Bits | Description                           |
|------|---------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only.          |
| 7:0  | <b>RevID: revision ID.</b> Read-only. |

### D1F1x0C Header Type

Reset: 0080\_0000h.

| Bits  | Description                                                                                                 |
|-------|-------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>BIST.</b> Read-only. These bits are fixed at their default values.                                       |
| 23:16 | <b>HeaderTypeReg.</b> Read-only. 80h=Type 0 multi-function device.                                          |
| 15:8  | <b>LatencyTimer.</b> Read-only. These bits are fixed at their default value.                                |
| 7:0   | <b>CacheLineSize.</b> Read-write. This field specifies the system cache line size in units of double words. |

### D1F1x10 Audio Registers Base Address

Reset: 0000\_0000h.

| Bits  | Description                                                                           |
|-------|---------------------------------------------------------------------------------------|
| 31:14 | <b>BaseAddr: base address.</b> Read-write.                                            |
| 13:4  | Reserved.                                                                             |
| 3     | <b>Pref: prefetchable.</b> Read-only. 0=Non-prefetchable memory region.               |
| 2:1   | <b>Type: base address register type.</b> Read-only. 00b=32-bit base address register. |
| 0     | <b>MemSpace: memory space type.</b> Read-only. 0=Memory mapped base address.          |

### D1F1x14 Base Address 1

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x18 Base Address 2**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x1C Base Address 3**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x20 Base Address 4**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x24 Base Address 5**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x2C Subsystem and Subvendor ID**Reset: 0000\_0000h. This register can be modified through [D1F1x4C](#).

| Bits  | Description                           |
|-------|---------------------------------------|
| 31:16 | <b>SubsystemID</b> . Read-only.       |
| 15:0  | <b>SubsystemVendorID</b> . Read-only. |

**D1F1x30 Expansion ROM Base Address**

Reset: 0000\_0000h.

| Bits | Description |
|------|-------------|
| 31:0 | Reserved.   |

**D1F1x34 Capabilities Pointer**

Reset: 0000\_0050h.

| Bits | Description                                                               |
|------|---------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                 |
| 7:0  | <b>CapPtr: capabilities pointer.</b> Read-only. Pointer to PM capability. |

**D1F1x3C Interrupt Line**

Reset: 0000\_02FFh.

| Bits  | Description                                                                                                          |
|-------|----------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                            |
| 15:8  | <b>InterruptPin: interrupt pin.</b> Read-only. This field identifies the legacy interrupt message the function uses. |
| 7:0   | <b>InterruptLine: interrupt line.</b> Read-write. This field contains the interrupt line routing information.        |

**D1F1x4C Subsystem and Subvendor ID Mirror**

Reset: 0000\_0000h.

| Bits  | Description                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>SubsystemID.</b> Read-write. This field sets the value in the corresponding field in <a href="#">D1F1x2C</a> .       |
| 15:0  | <b>SubsystemVendorID.</b> Read-write. This field sets the value in the corresponding field in <a href="#">D1F1x2C</a> . |

**D1F1x50 Power Management Capability**

| Bits  | Description                                                                                                                            |
|-------|----------------------------------------------------------------------------------------------------------------------------------------|
| 31:27 | <b>PmeSupport.</b> Value: 0_0000b. Indicates that there is no PME support.                                                             |
| 26    | <b>D2Support: D2 support.</b> Value: 1. D2 is supported                                                                                |
| 25    | <b>D1Support: D1 support.</b> Value: 1. D1 is supported                                                                                |
| 24:22 | <b>AuxCurrent: auxiliary current.</b> Value: 0.                                                                                        |
| 21    | <b>DevSpecificInit: device specific initialization.</b> Value: 0. Indicates that there is no device specific initialization necessary. |
| 20    | Reserved.                                                                                                                              |
| 19    | <b>PmeClock.</b> Value: 0.                                                                                                             |
| 18:16 | <b>Version: version.</b> Value: 011b.                                                                                                  |
| 15:8  | <b>NextPtr: next pointer.</b> Value: IF ( <a href="#">D0F0xD4_x0130_14BE</a> [StrapBifMsiDis]==0) THEN A0h. ELSE 00h. ENDIF.           |
| 7:0   | <b>CapID: capability ID.</b> Value: 01h. Indicates that the capability structure is a PCI power management data structure.             |

**D1F1x54 Power Management Control and Status**

Reset: 0000\_0000h.

| Bits     | Description                                                                                                                                                                                                                                                                                                                                                                  |      |            |     |    |          |          |     |       |

### D1F1x68 Link Control and Status

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>LinkAutonomousBWStatus: link autonomous bandwidth status.</b> Read-only.                                                                                                                                                                                                                                                                        |
| 30    | <b>LinkBWManagementStatus: link bandwidth management status.</b> Read-only.                                                                                                                                                                                                                                                                        |
| 29    | <b>DLActive: data link layer link active.</b> Read-only. This bit indicates the status of the data link control and management state machine. Reads return a 1 to indicate the DL_Active state, otherwise 0 is returned.                                                                                                                           |
| 28    | <b>SlotClockCfg: slot clock configuration.</b> Read-only. 1=The root port uses the same clock that the platform provides.                                                                                                                                                                                                                          |
| 27    | <b>LinkTraining: link training.</b> Read-only. 1=Indicates that the physical layer link training state machine is in the configuration or recovery state, or that 1b was written to the RetrainLink bit but link training has not yet begun. Hardware clears this bit when the link training state machine exits the configuration/recovery state. |
| 26    | Reserved.                                                                                                                                                                                                                                                                                                                                          |
| 25:20 | <b>NegotiatedLinkWidth: negotiated link width.</b> Read-only. This field indicates the negotiated width of the given PCI Express link.                                                                                                                                                                                                             |

**D1F1xA8 MSI Message Address High**

Reset: 0000\_0000h.

| Bits | Description                                                                                                                           |
|------|---------------------------------------------------------------------------------------------------------------------------------------|
| 31:8 | Reserved.                                                                                                                             |
| 7:0  | <b>MsiMsgAddrHi: MSI message address.</b> Read-write. This register specifies the upper 8-bits of the MSI address in 64 bit MSI mode. |

**D1F1xAC MSI Message Data**

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                       |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:16 | Reserved.                                                                                                                                                         |
| 15:0  | <b>MsiData: MSI message data.</b> Read-write. This register specifies lower 16 bits of data for the MSI memory write transaction. The upper 16 bits are always 0. |

**D1F1x100 Vendor Specific Enhanced Capability**

Reset: 0111\_000Bh.

| Bits  | Description                                   |
|-------|-----------------------------------------------|
| 31:20 | <b>NextPtr: next pointer.</b> Read-only.      |
| 19:16 | <b>CapVer: capability version.</b> Read-only. |
| 15:0  | <b>CapID: capability ID.</b> Read-only.       |

**D1F1x104 Vendor Specific Header**

Reset: 0101\_0001h.

| Bits  | Description                                                             |
|-------|-------------------------------------------------------------------------|
| 31:20 | <b>VsecLen: vendor specific enhanced next pointer.</b> Read-only.       |
| 19:16 | <b>VsecRev: vendor specific enhanced capability version.</b> Read-only. |
| 15:0  | <b>VsecID: vendor specific enhanced capability ID.</b> Read-only.       |

**D1F1x108 Vendor Specific 1**

---

Reset: 0000\_0000h.

| Bits | Description                          |
|------|--------------------------------------|
| 31:0 | <b>Scratch: scratch.</b> Read-write. |

**D1F1x10C Vendor Specific 2**

---

Reset: 0000\_0000h.

| Bits | Description                          |
|------|--------------------------------------|
| 31:0 | <b>Scratch: scratch.</b> Read-write. |

### 3.7 Device 2 Function 0 (Host Bridge) Configuration Registers

See 3.1 [Register Descriptions and Mnemonics] for a description of the register naming convention. See 2.7 [Configuration Space] for details about how to access this space. D2F0 registers do not control any hardware. They ensure that software can configure functions 1 through 4.

#### D2F0x00 Device/Vendor ID (Host Bridge)

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID: device ID.</b> Read-only. Value: 1538h. |
| 15:0  | <b>VendorID: vendor ID.</b> Read-only. Value: 1022h. |

#### D2F0x04 Status/Command

Reset: 0000\_0000h.

| Bits  | Description                              |
|-------|------------------------------------------|
| 31:16 | <b>Status.</b> Read-only. Tied to 0x0h.  |
| 15:0  | <b>Command.</b> Read-only. Tied to 0x0h. |

#### D2F0x08 Class Code/Revision ID

Reset: 0600\_0000h.

| Bits | Description                                                  |
|------|--------------------------------------------------------------|
| 31:8 | <b>ClassCode: class code.</b> Read-only. Tied to 0x06_0000h. |
| 7:0  | <b>RevId: revision identifier.</b> Read-only. Tied to 0x0h.  |

#### D2F0x0C Header Type

Reset: 0080\_0000h.

| Bits  | Description                                                                                                                                                          |

| 8     | <b>SerrEn:</b> system error enable. Read-write. 1=System error reporting enabled.                                                                        |
| 7     | <b>Stepping:</b> Stepping control. Read-only.                                                                                                            |
| 6     | <b>ParityErrorEn:</b> parity error response enable. Read-write.                                                                                          |
| 5     | <b>PalSnoopEn:</b> VGA palette snoop enable. Read-only.                                                                                                  |
| 4     | <b>MemWriteInvalidateEn:</b> memory write and invalidate enable. Read-only.                                                                              |
| 3     | <b>SpecialCycleEn:</b> special cycle enable. Read-only.                                                                                                  |
| 2     | <b>BusMasterEn:</b> bus master enable. Read-write.                                                                                                       |
| 1     | <b>MemAccessEn:</b> IO access enable. Read-write. This bit controls if memory accesses targeting this device are accepted or not. 1=Enabled. 0=Disabled. |
| 0     | <b>IoAccessEn:</b> IO access enable. Read-write. This bit controls if IO accesses targeting this device are accepted or not. 1=Enabled. 0=Disabled.      |

### D2F[5:1]x08 Class Code/Revision ID Register

Reset: 0604\_00xxh.

| Bits | Description                                                                                           |
|------|-------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only.                                                                 |

### D2F[5:1]x0C Header Type Register

Reset: 0001\_0000h.

| Bits  | Description                                                                                                                   |
|-------|-------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>BIST.</b> Read-only. These bits are fixed at their default values.                                                         |
| 23    | <b>DeviceType.</b> Read-only. 0=Single function device. 1=Multi-function device.                                              |
| 22:16 | <b>HeaderType.</b> Read-only. These bits are fixed at their default values. Indicates a Type 0 or Type 1 configuration space. |
| 15:8  | <b>LatencyTimer.</b> Read-only. This field does not control any hardware.                                                     |
| 7:0   | <b>CacheLineSize.</b> Read-write.                                                                                             |

**D2F[5:1]x18 Bus Number and Secondary Latency Register**

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                        |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:24 | <b>SecondaryLatencyTimer: secondary latency timer.</b> Read-only. This field is always 0.                                                          |
| 23:16 | <b>SubBusNumber: subordinate number.</b> Read-write. This field contains the highest-numbered bus that exists on the secondary side of the bridge. |
| 15:8  | <b>SecondaryBus: secondary bus number.</b> Read-write. This field defines the bus number of the secondary bus interface.                           |
| 7:0   | <b>PrimaryBus: primary bus number.</b> Read-write. This field defines the bus number of the primary bus interface.                                 |

**D2F[5:1]x1C IO Base and Secondary Status Register**

Reset: 0000\_0101h.

| Bits  | Description                                                                                                                                                                                  |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>ParityErrorDetected: detected parity error.</b> Read; Write-1-to-clear. A Poisoned TLP was received regardless of the state of the <a href="#">D2F[5:1]x04[ParityErrorEn]</a> .           |
| 30    | <b>ReceivedSystemError: signaled system error.</b> Read; Write-1-to-clear. 1=A System Error was detected.                                                                                    |
| 29    | <b>ReceivedMasterAbort: received master abort.</b> Read; Write-1-to-clear. 1=A CPU transaction is terminated due to a master-abort.                                                          |

### D2F[5:1]x68 IO Link Control and Status Register

Reset: 1001\_0000h.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                              |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>LinkAutonomousBWStatus: link autonomous bandwidth status.</b> IF (D2F[5:1]x64[LinkBWNotificationCap]==0) THEN Read-only. ELSE Read-write; updated-by-hardware. ENDIF.                                                                                                                                                                                                                 |
| 30   | <b>LinkBWManagementStatus: link bandwidth management status.</b> IF (D2F[5:1]x64[LinkBWNotificationCap]==0) THEN Read-only. ELSE Read-write; updated-by-hardware. ENDIF.                                                                                                                                                                                                                 |
| 29   | <b>DLActive: data link layer link active.</b> Read-only; updated-by-hardware. This bit indicates the status of the data link control and management state machine. 1=DL_Active state. 0=All other states.                                                                                                                                                                                |
| 28   | <b>SlotClockCfg: slot clock configuration.</b> Read-only; updated-by-hardware. 1=The root port uses the same clock that the platform provides.                                                                                                                                                                                                                                           |
| 27   | <b>LinkTraining: link training.</b> Read-only; updated-by-hardware. This read-only bit indicates that the physical layer link training state machine is in the configuration or recovery state, or that 1b was written to the RetrainLink bit but link training has not yet begun. Hardware clears this bit when the link training state machine exits the configuration/recovery state. |

Read-write. 1=Enables the root port returning configuration request retry status (CRS) completion status to software.                                                                                                                                                       |
| 3    | <b>PmIntEn:</b> PME interrupt enable. Read-write. 1=Enables interrupt generation upon receipt of a PME message as reflected <a href="#">D2F[5:1]x78[PmeStatus]</a> . A PME interrupt is also generated if <a href="#">D2F[5:1]x78[PmeStatus]=1</a> and this bit is set by software.                                                  |
| 2    | <b>SerrOnFatalErrEn:</b> system error on fatal error enable. Read-write. 1=Indicates that a system error should be generated if a fatal error (ERR_FATAL) is reported by any of the devices in the hierarchy associated with this root port, or by the root port itself.                                                             |
| 1    | <b>SerrOnNonFatalErrEn:</b> system error on non-fatal error enable. Read-write. 1=Indicates that a system error should be generated if a non-fatal error (ERR_NONFATAL) is reported by any of the devices in the hierarchy associated with this root port, or by the root port itself. See <a href="#">2.13.7.8 [SERR Message]</a> . |
| 0    | <b>SerrOnCorrErrEn:</b> system error on correctable error enable. Read-write. 1=Indicates that a system error should be generated if a correctable error (ERR_COR) is reported by any of the devices in the hierarchy associated with this root port, or by the root port itself. See <a href="#">2.13.7.8 [SERR Message]</a> .      |

### D2F[5:1]x78 Root Complex Status Register

Reset: 0000\_0000h.

| Bits  | Description                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:18 | Reserved.                                                                                                                                                                                                                                                                                                                               |
| 17    | <b>PmePending:</b> PME pending. Read-only. This bit indicates that another PME is pending when PmeStatus is set. When PmeStatus is cleared by software; the PME is delivered by hardware by setting the PmeStatus bit again and updating the requestor ID appropriately. PmePending is cleared by hardware if no more PMEs are pending. |
| 16    | <b>PmeStatus:</b> pme status. Read; Write-1-to-clear. This bit indicates that PME was asserted by the requestor ID indicated in the PmeRequestorID field. Subsequent PMEs are kept pending until PmeStatus is cleared by writing a 1.                                                                                                   |
| 15:0  | <b>PmeRequestorId:</b> pme requestor ID. Read-only. This field indicates the PCI requestor ID of the last PME requestor.                                                                                                                                                                                                                |

**D2F[5:1]xE0 Root Port Index**

Reset: 0000\_0000h.

The index/data pair registers, [D2F\[5:1\]xE0](#) and [D2F\[5:1\]xE4](#), are used to access the registers at [D2F\[5:1\]xE4\\_x\[FF:00\]](#). To access any of these registers, the address is first written into the index register, [D2F\[5:1\]xE0](#), and then the data is read from or written to the data register, [D2F\[5:1\]xE4](#).

| 15:0  | <b>ErrCorlSrcID: ERR_COR source identification.</b> Read-only. Loaded with the requestor ID indicated in the received ERR_COR message when <a href="#">D2F[5:1]x180[ErrCorrRcvd]</a> is not already set.                                                    |

### 3.9 Device 18h Function 0 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F0x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 1530h. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F0x04 Status/Command

| Bits  | Description                                                                                                         |
|-------|---------------------------------------------------------------------------------------------------------------------|
| 31:16 | <b>Status.</b> Read-only. Value: 0010h. Bit[20] is set to indicate the existence of a PCI-defined capability block. |
| 15:0  | <b>Command.</b> Read-only. Value: 0000h.                                                                            |

#### D18F0x08 Class Code/Revision ID

| Bits | Description                                                                                                           |
|------|-----------------------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Value: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only. Value: 00h.                                                                     |

#### D18F0x0C Header Type

Read-only. Value: 0080\_0000h.

| Bits | Description                                                                                                                                                   |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> These bits are fixed at their default values. The header type field indicates that there are multiple functions present in this device. |

#### D18F0x34 Capabilities Pointer

| Bits | Description                                                 |
|------|-------------------------------------------------------------|
| 31:8 | Reserved.                                                   |
| 7:0  | <b>CapPtr:</b> capabilities pointer. Read-only. Value: 00h. |

#### D18F0x[5C:40] Routing Table

Reset: 0004\_0201h. As each packet is processed by the node, it is routed to the appropriate links, or remains in the node that is processing the packet, based on the source/destination node and the type of packet being pro-

cessed. The destination of requests and responses determines which of these eight registers is used to route the packet; the source of probes and broadcasts determines which of these eight registers is used to route the packet. Once the routing table register is identified, the packet is routed to the destinations based on the state of the field (in that routing table register) that corresponds to the packet type.

**Table 100: Register Mapping for D18F0x[5C:40]**

| Register      | Function |
|---------------|----------|
| D18F0x40      | Node 0   |
| D18F0x[5C:44] | Reserved |

| Bits | Description |
|------|-------------|
|------|-------------|

#### D18F0x60 Node ID

| Bits        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                               |             |                    |     |        |         |                         |     |         |         |          |

| 20    | <b>SeqIdSrcNodeEn: sequence ID source node enable</b> . Read-write. Reset: 0. 1=The source node ID of requests is provided in the SeqID field of the corresponding downstream IO link request packets. This may be useful for debug applications, in order to match downstream packets with their originating node. For normal operation, this bit should be cleared. Correct ordering of requests between different nodes is not ensured when this bit is set. Semaphore sharing between differing nodes may not work properly in systems which are capable of processing IO requests with differing non-zero SeqIds out of request order. |      |             |     |          |     |              |     |              |     |              |
| 19    | <b>ApicExtSpur: APIC extended spurious vector enable</b> . Read-write. Reset: 0. This enables the extended APIC spurious vector functionality; it affects APICF0[Vector]. 0=The lower 4 bits of the spurious vector are read-only 1111b. 1=The lower 4 bits of the spurious vector are writable.                                                                                                                                                                                                                                                                                                                                            |      |             |     |          |     |              |     |              |     |              |
| 18    | <b>ApicExtId: APIC extended ID enable</b> . Read-write. Reset: 0. Enables the extended APIC ID functionality. 0=APIC ID is 4 bits. 1=APIC ID is 8 bits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |             |     |          |     |              |     |              |     |              |
| 17    | <b>ApicExtBrdCst: APIC extended broadcast enable</b> . Read-write. Reset: 0. Enables the extended APIC broadcast functionality. 0=APIC broadcast is 0Fh. 1=APIC broadcast is FFh. If ApicExt-BrdCst=1 then software must assert ApicExtId.                                                                                                                                                                                                                                                                                                                                                                                                  |      |             |     |          |     |              |     |              |     |              |
| 16    | <b>LintEn: local interrupt conversion enable</b> . Read-write. Reset: 0. 1=Enables the conversion of broadcast ExtInt and NMI interrupt requests to LINT0 and LINT1 local interrupts, respectively, before delivering to the local APIC. This conversion only takes place if the local APIC is hardware enabled. LINT0 and LINT1 are controlled by APIC3[60:50]. 0=ExtInt/NMI interrupts delivered unchanged.                                                                                                                                                                                                                               |      |             |     |          |     |              |     |              |     |              |
| 15    | <b>LimitCldtCfg: limit coherent link configuration space range</b> . Read-write. Reset: 0. BIOS: 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |             |     |          |     |              |     |              |     |              |

### D18F0x[E4,C4,A4,84] Link Control

Table 101: [Register Mapping](#) for D18F0x[E4,C4,A4,84]

| Register         | Function   |
|------------------|------------|
| D18F0x84         | ONION Link |
| D18F0x[E4,C4,A4] | Reserved   |

This register is derived from the link control register defined in the link specification.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 15    | <b>Addr64BitEn: 64-bit address packet enable.</b> Read-write. Reset: 0000b. 1=Requests to addresses greater than FF_FFFF_FFFFh are supported by this IO link. 0=Requests to addresses greater than FF_FFFF_FFFFh are master aborted as if the end of chain was reached. BIOS is required to ensure that the link-specification-defined “64 Bit Address Feature” bit in the device on the other side of the link is set prior to setting this bit. For coherent links, this bit is unused. <a href="#">D18F0x68</a> [CHtExtAddrEn] is required to be set if this bit is set for any IO link. The link specification indicates that this bit is cleared by a warm reset; therefore this bit may be in a different state than an IO device on the other side of the link after a warm reset; care should be taken by BIOS to place devices on both sides of the link in the same state after a warm reset, before any packets to the high-order addresses enabled by this bit are generated. |
| 14:13 | Reserved. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 12    | <b>IsocEn: isochronous flow-control mode enable.</b> Read-write. Reset: 0b. BIOS: 1 if the link is an ONION Link. This bit is set to place the link into isochronous flow-control mode (IFCM), as defined by the link specification. 1=IFCM. 0=Normal flow-control mode. See <a href="#">D18F0x6C</a> [ApplyIsocModeEnNow].                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### D18F0x[F0,D0,B0,90] Link Base Channel Buffer Count

Read-write; Reset-applied.

Table 103: Register Mapping for D18F0x[F0,D0,B0,90]

| Register         | Function   |
|------------------|------------|
| D18F0x90         | ONION Link |
| D18F0x[F0,D0,B0] | Reserved   |

D18F0x[F0,D0,B0,90] and D18F0x[F4,D4,B4,94] specify the *hard-allocated* link flow-control buffer counts in each virtual channel available to the transmitter at the other end of the link; it also provides the *free buffers* that may be used by any of the virtual channels, as needed. Base channel buffers are specified in D18F0x[F0,D0,B0,90]; isochronous buffer counts (if in IFCM) are specified in D18F0x[F4,D4,B4,94]. For all fields that specify buffer counts in D18F0x[F0,D0,B0,90] and D18F0x[F4,D4,B4,94], if the link is ganged, then the number of buffers allocated is 2 times the value of the field; If the link is unganged, then the number of buffers allocated is the value of the field.

The cold or warm reset value is determined by whether the link initializes, whether the link is IO/coherent, whether the link is ganged/unganged, and whether the settings are locked by LockBc. Out of cold reset, the processor allocates a minimal number of buffers that is smaller than the default values in the register. BIOS must use D18F0x6C[RlsLnkFullTokCntImm] or D18F0x6C[RlsLnkFullTokCntOnRst] for the values in the register to take effect. This is necessary even if the values are unchanged from the default values.

The hard-allocated buffer counts are transmitted to the device at the other end of the link in buffer release messages after link initialization. The remaining buffers are held in the free list (specified by FreeData and FreeCmd) used to optimize buffer usage. When a transaction is received, if a free-list buffer is available, it is used for storage instead of one of the hard allocated buffers; as a result, a buffer release (for one of the hard allocated buffers used by the incoming request) can be immediately sent back to the device at the other end of the link without waiting for the transaction to be routed beyond the flow-control buffers.

**Table 104: Link Buffer Definitions**

| Term            | Definition                                        |
|-----------------|---------------------------------------------------|
| <b>LpbSize</b>  | Link Packet Command Buffer size.<br>LpbSize = 24. |
| <b>LpbdSize</b> | Link Packet Data Buffer size.<br>LpbdSize = 16.   |
| <b>LcsSize</b>  | Link Command Scheduler size.<br>LcsSize = 32.     |

Buffer allocation rules:

- The total number of command buffers allocated in the base and isochronous registers of a link cannot exceed **LpbSize**:
  - Rule:  $(D18F0x[F0,D0,B0,90][NpReqCmd] + D18F0x[F0,D0,B0,90][PReq] + D18F0x[F0,D0,B0,90][RspCmd] + D18F0x[F0,D0,B0,90][ProbeCmd] + D18F0x[F0,D0,B0,90][FreeCmd] + D18F0x[F4,D4,B4,94][IsocNpReqCmd] + D18F0x[F4,D4,B4,94][IsocPReq] + D18F0x[F4,D4,B4,94][IsocRspCmd]) \leq LpbSize$ .
- The total number of data buffers allocated in the base and isochronous registers of a link cannot exceed **LpbdSize**:
  - Rule:  $(D18F0x[F0,D0,B0,90][NpReqData] + D18F0x[F0,D0,B0,90][RspData] + D18F0x[F0,D0,B0,90][PReq] + D18F0x[F0,D0,B0,90][FreeData] + D18F0x[F4,D4,B4,94][IsocPReq] + D18F0x[F4,D4,B4,94][IsocNpReqData] + D18F0x[F4,D4,B4,94][IsocRspData]) \leq LpbdSize$ .
- The total number of hard allocated command buffers cannot exceed **LcsSize**.
  - Rule:  $(D18F0x[F0,D0,B0,90][ProbeCmd] + D18F0x[F0,D0,B0,90][RspCmd] + D18F0x[F0,D0,B0,90][PReq] + D18F0x[F0,D0,B0,90][NpReqCmd] + D18F0x[F4,D4,B4,94][IsocRspCmd] + D18F0x[F4,D4,B4,94][IsocPReq] + D18F0x[F4,D4,B4,94][IsocNpReqCmd]) \leq LcsSize$ .

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31    | <b>LockBc: lock buffer count register.</b><br>Cold reset: 0.<br>BIOS: 1.<br>1=The buffer count registers, <a href="#">D18F0x[F0,D0,B0,90]</a> and <a href="#">D18F0x[F4,D4,B4,94]</a> are locked such that warm resets do not place the registers back to their default value. Setting this bit does not prevent the buffer counts from being updated after a warm reset based on the value of the buffer counts before the warm reset. 0=Upon warm reset, the buffer count registers return to their default value after the link initializes regardless of the value before the warm reset. |

### D18F0x[11C,118,114,110] Link Clumping Enable

Reset: 0000\_0000h. D18F0x[11C,118,114,110] are associated with the whole link if it is ganged or sublink 0 if

it is ungangued; If the node does not support a link, then the corresponding register addresses become reserved.

Table 107: [Register Mapping](#) for [D18F0x\[11C,118,114,110\]](#)

| Register      | Function   |
|---------------|------------|
| D18F0x110     | ONION Link |
| D18F0x11[C:4] | Reserved   |

These registers specify how UnitIDs of upstream non-posted requests may be clumped per the link specification. The processor does not clump requests that it generates in the downstream direction.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:1 | <b>ClumpEn.</b> Read-write. Each bit of this register corresponds to a link UnitID number. E.g., bit 2 corresponds to UnitID 02h, etc. 1=The specified UnitID is ordered in the same group as the specified UnitID - 1. For example if this register is programmed to 0000_00C0h, then UnitIDs 7h, 6h, and 5h are all ordered as if they are part of the same UnitID. This is used to allow more than 32 tags to be assigned to a single stream for the purposes of ordering. Bit 1 must be set by BIOS for the ONION link. Other bits must be set per GNB requirements. (See <a href="#">D0F0x98_x3A.</a> ) For ONIONPlus links, BIOS must program this field to 7FFF_FFF9h. |

| 31:8 | <b>ClassCode.</b> Read-only. Value: 060000h. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID: revision ID.</b> Read-only. Value: 00h. Processor revision. 00h=A0.                                         |

#### D18F1x0C Header Type

Reset: 0080\_0000h.

| Bits | Description                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> Read-only. These bits are fixed at their default values. The header type field indicates that there are multiple functions present in this device. |

#### D18F1x[17C:140,7C:40] DRAM Base/Limit

The following sets of registers specify the DRAM address ranges:

Table 110: Register Mapping for D18F1x[17C:140,7C:40]

| Function | Base Low                      | Limit Low                     | Base High                       | Limit High                      |
|----------|-------------------------------|-------------------------------|---------------------------------|---------------------------------|
| Range 0  | D18F1x40                      | D18F1x44                      | D18F1x140                       | D18F1x144                       |
| Reserved | D18F1x48,<br>D18F1x[7:5][8,0] | D18F1x4C,<br>D18F1x[7:5][C,4] | D18F1x148,<br>D18F1x1[7:5][8,0] | D18F1x14C,<br>D18F1x1[7:5][C,4] |

Transaction addresses that are within the specified base/limit range are routed to the DstNode. See 2.8.2 [NB Routing].

DRAM mapping rules:

F1x0XX registers provide the low address bits. F1x1XX registers are reserved.

- Transaction addresses are within the defined range if:  
 $\{\text{DramBase}[39:24], 00\_0000h\} \leq \text{address}[39:0] \leq \{\text{DramLimit}[39:24], FF\_FFFFh\}$ .
- DRAM regions must not overlap each other.
- Accesses to addresses that map to both DRAM, as specified by the DRAM base and limit registers (F1x[1, 0][7C:40]), and MMIO, as specified by D18F1x[2CC:2A0,1CC:180,BC:80], are routed to MMIO only.

- Programming of the DRAM address maps must be consistent with the Memory-Type Range Registers (MTRRs) and the top of memory registers, [MSRC001\\_001A](#) and [MSRC001\\_001D](#). CPU accesses only hit within the DRAM address maps if the corresponding MTRR is of type DRAM. Accesses from IO links are routed based on the DRAM base and limit registers (F1x[1, 0][7C:40]) only.
- The appropriate RE or WE bit(s) must be set. When initializing a base/limit pair, the BIOS must write the [limit] register before either the RE or WE bit is set. When changing a base/limit pair that is already enabled, the BIOS should clear RE and WE before changing the address range.
- See [2.8.2.1.1 \[DRAM and MMIO Memory Space\]](#).

When memory hoisting is enabled in a node via [D18F1x2\[1,0\]\[8,0\]\[LgcyMmioHoleEn\]](#), the corresponding BaseAddr/LimitAddr should be configured to account for the memory hoisted above the hole. See [2.9.10 \[Memory Hoisting\]](#).

#### **D18F1x[7:4][8,0] DRAM Base Low**

IF ([D18F2x118\[LockDramCfg\]](#)) THEN Read-only. ELSE Read-write. ENDIF. IF ([BootFromDRAM](#) && REG==D18F1x40) THEN Cold reset: 0000\_0003h. ELSE Reset: 0000\_0000h. ENDIF.

| Range 11 | D18F1x1B8            | D18F1x1BC            | Reserved             |
| Reserved | D18F1x2[B8,B0,A8,A0] | D18F1x2[BC,B4,AC,A4] | Reserved             |

Transaction addresses that are within the specified base/limit range are routed to the node specified by DstNode and the link specified by DstLink. See [2.8.2 \[NB Routing\]](#).

#### MMIO mapping rules:

- Transaction addresses are within the defined range if:  
 $\{\text{MMIOBase}[39:16], 0000\text{h}\} \leq \text{address}[39:0] \leq \{\text{MMIOLimit}[39:16], \text{FFFFh}\}.$
- MMIO regions must not overlap each other.
- Accesses to addresses that map to both DRAM, as specified by the DRAM base and limit registers (see [D18F1x\[17C:140,7C:40\]](#)), and MMIO, as specified by the memory mapped IO base and limit registers ([F1x\[BC:80\]](#)), are routed to MMIO only.
- Programming of the MMIO address maps must be consistent with the Memory-Type Range Registers (MTRRs) and the top of memory registers, [MSRC001\\_001A](#) and [MSRC001\\_001D](#). CPU accesses only hit within the MMIO address maps if the corresponding MTRR is of type IO. Accesses from IO links are routed based on [D18F1x\[2CC:2A0,1CC:180,BC:80\]](#).
- The appropriate RE or WE bit(s) must be set. When initializing a base/limit pair, the BIOS must write the limit register before either the RE or WE bit is set. When changing a base/limit pair that is already enabled, the BIOS should clear RE and WE before changing the address range.
- Scenarios in which the address space of multiple MMIO ranges target the same IO device is supported.

- See [2.8.2.1.1 \[DRAM and MMIO Memory Space\]](#).

| 31:8 | <b>MMIOLimit[39:16]: MMIO limit address register bits[39:16].</b> Read-write. Reset: 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |      |             |     |        |     |        |     |        |     |        |
| 7    | <p><b>NP: non-posted.</b> Read-write. Reset: 0. 1=CPU write requests to this MMIO range are passed through the non-posted channel. This may be used to force writes to be non-posted for MMIO regions which map to the legacy ISA/LPC bus, or in conjunction with <a href="#">D18F0x68[DsNpReqLmt]</a> in order to allow downstream CPU requests to be counted and thereby limited to a specified number. This latter use of the NP bit may be used to avoid loop deadlock scenarios in systems that implement a region in an IO device that reflects downstream accesses back upstream. See the link summary of deadlock scenarios for more information. 0=CPU writes to this MMIO range use the posted channel. This bit does not affect requests that come from IO links (the virtual channel of the request is specified by the IO request).</p> <p>If two MMIO ranges target the same IO device and the NP bit is set differently in both ranges, unexpected transaction ordering effects are possible. In particular, using PCI- and IO-link-defined producer-consumer semantics, if a producer (e.g., the processor) writes data using a non-posted MMIO range followed by a flag to a posted MMIO range, then it is possible for the device to see the flag updated before the data is updated.</p> |      |             |     |        |     |        |     |        |     |        |
| 6    | <b>DstSubLink: destination sublink.</b> Read-write. Reset: 0. When a link is unganged, this bit specifies the destination sublink of the link specified by the memory mapped IO base and limit registers F1x[BC:80][DstLink]. 0=The destination link is sublink 0. 1=The destination link is sublink 1. If the link is ganged, then this bit must be low.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |      |             |     |        |     |        |     |        |     |        |
| 5:4  | <p><b>DstLink: destination link ID.</b> Read-write. Reset: 0. | 2:0  | <b>DstNode: destination node ID bits.</b> Read-write. Reset: 0. For transactions within this MMIO range, this field specifies the destination node ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |      |             |     |        |     |        |     |        |     |        |

### D18F1x[DC:C0] IO-Space Base/Limit

The IO-space base and limit registers, [D18F1x\[DC:C0\]](#), specify the mapping from IO addresses to the corresponding node and IO link for transactions resulting from x86-defined IN and OUT instructions. IO address ranges are specified by upto 8 sets of base/limit registers. The first set is F1xC0 and F1xC4, the second

set is F1xC8 and F1xCC, and so forth. Transaction addresses that are within the specified base/limit range are routed to the node specified by DstNode and the link specified by DstLink. See [2.8.2 \[NB Routing\]](#).

IO mapping rules:

- IO-space transaction addresses are within the defined range if:  
{IOBase[24:12], 000h} <= address <= {IOLimit[24:12], FFFh} and as specified by the IE bit; or  
if the address is in the range specified by the VE bits.
- IO regions must not overlap each other.
- The appropriate RE or WE bit(s) must be set.
- See [2.8.2.1.2 \[IO Space\]](#).

| 5     | <b>IE: ISA enable.</b> Read-write. Reset: 0. 1=The IO-space address window is limited to the first 256 B of each 1 KB block specified; this only applies to the first 64 KB of IO space. 0=The PCI IO window is not limited in this way.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 4     | <b>VE: VGA enable.</b> Read-write. Reset: 0. 1=Include IO-space transactions targeting the VGA-compatible address space within the IO-space window of this base/limit pair. These include IO accesses in which address bits[9:0] range from 3B0h to 3BBh or 3C0h to 3DFh (address bits[15:10] are not decoded); this only applies to the first 64 KB of IO space; i.e., address bits[24:16] must be low). 0=IO-space transactions targeting VGA-compatible address ranges are not added to the IO-space window. This bit should only ever be set in one register. The MMIO range associated with the VGA enable bit in the PCI specification is NOT included in the VE bit definition; to map this range to an IO link, see <a href="#">D18F1xF4 [VGA Enable]</a> . When <a href="#">D18F1xF4[VE]</a> is set, the state of this bit is ignored. |

| 2:0   | <b>DstNode: destination node ID bits.</b> Read-write. Reset: 0. For transactions within this IO-space range, this field specifies the destination node ID.                                                                                                                                                                                                                                                   |      |             |     |        |     |        |     |        |     |        |

**D18F1x[1DC:1D0,EC:E0] Configuration Map**

D18F1x[1DC:1D0,EC:E0] specify the mapping from configuration address to the corresponding node and IO link. Configuration address ranges are specified by upto 8 pairs of base/limit registers. Transaction addresses that are within the specified base/limit range are routed to the node specified by DstNode and the link specified by DstLink. See 2.8.2 [NB Routing].

Table 118: Register Mapping for D18F1x[1DC:1D0,EC:E0]

| Register       | Function |
|----------------|----------|
| D18F1xE0       | Range 0  |
| D18F1xE4       | Range 1  |
| D18F1xE8       | Range 2  |
| D18F1xEC       | Range 3  |
| D18F1x1[DC:D0] | Reserved |

Configuration space mapping rules:

- Configuration addresses (to “BusNo” and “Device” as specified by IOCF8 [IO-Space Configuration

[Address](#)] in the case of IO accesses or [2.7 \[Configuration Space\]](#) in the case of MMIO accesses) are within the defined range if:

( {BusNumBase[7:0]} <= BusNo <= {BusNumLimit[7:0]} ) & (DevCmpEn==0); or  
 ( {BusNumBase[4:0]} <= Device <= {BusNumLimit[4:0]} ) & (DevCmpEn==1) & (BusNo== 00h).

- Configuration regions must not overlap each other.
- The appropriate RE or WE bit(s) must be set.
- See [2.8.2.1.3 \[Configuration Space\]](#).

For transactions within the <a href="#">D18F1xF4[VE]</a> -defined range, this field specifies the destination node ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |             |     |        |     |        |     |        |     |        |
| 3     | <b>Lock.</b> Read-write. 1=All the bits in this register ( <a href="#">D18F1xF4</a> ) are read-only (including this bit).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |      |             |     |        |     |        |     |        |     |        |
| 1     | <b>NP: non-posted.</b> Read-write. 1=CPU write requests to the <a href="#">D18F1xF4[VE]</a> -defined MMIO range are passed through the non-posted channel. 0=CPU writes may be posted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                |      |             |     |        |     |        |     |        |     |        |
| 0     | <b>VE: VGA enable.</b> Read-write. 1=Transactions targeting the VGA-compatible address space are routed and controlled as specified by this register. The VGA-compatible address space is: (1) the MMIO range A_0000h through B_FFFFh; (2) IO-space accesses in which address bits[9:0] range from 3B0h to 3BBh or 3C0h to 3DFh (address bits[15:10] are not decoded; this only applies to the first 64 KB of IO space; i.e., address bits[24:16] must be low). 0=Transactions targeting the VGA-compatible address space are not affected by the state of this register. When this bit is set, the state of <a href="#">D18F1xF4[VE]</a> is ignored. |      |             |     |        |     |        |     |        |     |        |

### D18F1x120 DRAM Base System Address

IF ([D18F2x118\[LockDramCfg\]](#)) THEN Read-only. ELSE Read-write. ENDIF. Cold reset: 0000\_0000h.

[D18F1x120](#) and [D18F1x124](#) are required to specify the base and limit system address range of the DRAM connected to the local node.

DRAM accesses to the local node with physical address Addr[47:0] that are within the following range are directed to the DCTs:

{DramBaseAddr[47:27], 000\_0000h} <= Addr[47:0] <= {DramLimitAddr[47:27], 7FF\_FFFFh};

DRAM accesses to the local node that are outside of this range are master aborted.

The address of the DRAM transaction is normalized before passing it to the DCTs by subtracting DramBaseAddr.

This range is also used to specify the range of DRAM covered by the scrubber (see [D18F3x58](#) and [D18F3x5C](#)).

| Bits  | Description                 |
|-------|-----------------------------|
| 31:21 | Reserved. Read-write.       |
| 20:0  | <b>DramBaseAddr[47:27].</b> |

### D18F1x124 DRAM Limit System Address

IF ([D18F2x118\[LockDramCfg\]](#)) THEN Read-only. ELSE Read-write. ENDIF. See [D18F1x120 \[DRAM Base System Address\]](#).

| Bits | Description |
|------|-------------|
|------|-------------|

|       |                                                                                                                       |
|-------|-----------------------------------------------------------------------------------------------------------------------|
| 23:21 | Reserved. Read-write.                                                                                                 |
| 20:0  | <b>DramLimitAddr[47:27]</b> . IF ( <b>BootFromDRAM</b> ) THEN Cold reset: 00_003Fh. ELSE Cold reset: 1F_FFFFh. ENDIF. |

### D18F1x2[1C:00] DRAM Controller Base/Limit

The DRAM controller base and limit registers define a DRAM controller address range and specify the mapping of physical DRAM addresses to a DCT as selected by DctSel or DctIntLvEn. The following base/limit register pairs specify the address ranges:

Table 119: [Register Mapping](#) for D18F1x2[1C:00]

| Function | Base Address                | Limit Address               |
|----------|-----------------------------|-----------------------------|
| Range 0  | D18F1x200                   | D18F1x204                   |
| Reserved | D18F1x208,<br>D18F1x21[8,0] | D18F1x20C,<br>D18F1x21[C,4] |

BIOS should observe the following DCT configuration requirements:

- DRAM addresses are within the defined range if:  
{DctBaseAddr[39:27], 000b, 00\_0000h} <= address[39:0] <= {DctLimitAddr[39:27], 111b, FF\_FFFFh}.
- DCT base/limit address ranges must not overlap each other.
- A maximum of two address ranges may be mapped to a single DCT.

**Hoisting.** When memory hoisting is enabled via LegacyMmioHoleEn, the corresponding DctBaseAddr/DctLimitAddr should be configured to account for the memory hoisted above the hole. A contiguous memory hole should only be mapped by one DctBaseAddr/DctLimitAddr pair. See [2.9.10 \[Memory Hoisting\]](#).

### D18F1x2[1,0][8,0] DRAM Controller Base

IF (**D18F2x118[LockDramCfg]**) THEN Read-only. ELSE Read-write. ENDIF. Reset: 0000\_0000h.

Table 120: [Register Mapping](#) for D18F1x2[1,0][8,0]

### 3.11 Device 18h Function 2 Configuration Registers

See 3.1 [Register Descriptions and Mnemonics]. See 2.7 [Configuration Space].

#### D18F2x00 Device/Vendor ID

| Bits  | Description                                          |
|-------|------------------------------------------------------|
| 31:16 | <b>DeviceID:</b> device ID. Read-only. Value: 1532h. |
| 15:0  | <b>VendorID:</b> vendor ID. Read-only. Value: 1022h. |

#### D18F2x08 Class Code/Revision ID

Reset: 0600\_0000h.

| Bits | Description                                                                                           |
|------|-------------------------------------------------------------------------------------------------------|
| 31:8 | <b>ClassCode.</b> Read-only. Provides the host bridge class code as defined in the PCI specification. |
| 7:0  | <b>RevID:</b> revision ID. Read-only.                                                                 |

#### D18F2x0C Header Type

Reset: 0080\_0000h.

| Bits | Description                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31:0 | <b>HeaderTypeReg.</b> Read-only. These bits are fixed at their default values. The header type field indicates that there multiple functions present in this device. |

#### D18F2x[5C:40]\_dct[0] DRAM CS Base Address

IF (D18F2x118[LockDramCfg] & ~D18F3x12C[OverrideLockDramCfg]) THEN Read-only. ELSE Read-write. ENDIF. IF (BootFromDRAM && REG==D18F2x40\_dct[0]) THEN Cold reset: 0000\_0001h. ELSE Reset: 0000\_0000h. ENDIF. See 2.9.3 [DCT Configuration Registers].

These registers along with D18F2x[6C:60]\_dct[0] [DRAM CS Mask], translate DRAM request addresses (to a DRAM controller) into DRAM chip selects. Supported DIMM sizes are specified in D18F2x80\_dct[0] [DRAM Bank Address Mapping]. For more information on the DRAM controllers, see 2.9 [DRAM Controllers (DCTs)].

For each chip select, there is a DRAM CS Base Address register. For each CS pair there is a DRAM CS Mask Register. For each CS pair, an even CS must be populated if the odd CS is populated.

**Table 122: DIMM, Chip Select, and Register Mapping**

| Base Address Registers | Mask Register | Logical DIMM | Chip Select <sup>1</sup> |
|------------------------|---------------|--------------|--------------------------|
| D18F2x40_dct[x]        | F2x60         | 0            | BP_MEMCS[x]_L[0]         |
| D18F2x44_dct[x]        |               |              | BP_MEMCS[x]_L[1]         |

**Table 122: DIMM, Chip Select, and Register Mapping**

| Base Address Registers                          | Mask Register | Logical DIMM | Chip Select <sup>1</sup> |

| 1. See 2.9.4 [DDR Pad to Processor Pin Mapping] |               |              |                          |

The DRAM controller operates on the normalized physical address of the DRAM request. The normalized physical address includes all of the address bits that are supported by a DRAM controller. See 2.8 [Northbridge (NB)].

Each base address register specifies the starting normalized address of the block of memory associated with the chip select. Each mask register specifies the additional address bits that are consumed by the block of memory associated with the chip selects. If both chip selects of a DIMM are used, they must be the same size; in this case, a single mask register covers the address space consumed by both chip selects.

Lower-order address bits are provided in the base address and mask registers, as well. These allow memory to be interleaved between chip selects, such that contiguous physical addresses map to the same DRAM page of multiple chip selects. See 2.9.9.1 [Chip Select Interleaving]. The hardware supports the use of lower-order address bits to interleave chip selects if (1) the each chip select of the memory system spans the same amount of memory and (2) the number of chip selects of the memory system is a power of two.

System BIOS is required to assign the largest DIMM chip-select range to the lowest normalized address of the DRAM controller. As addresses increase, the chip-select size is required to remain constant or decrease. This is necessary to keep DIMM chip-select banks on aligned address boundaries, regardless as to the amount of address space covered by each chip select.

For each normalized address for requests that enters a DRAM controller, a ChipSelect[i] is asserted if:

```
CSEnable[i] &
({ (InputAddr[38:27] & ~AddrMask[i][38:27]),
 (InputAddr[21:11] & ~AddrMask[i][21:11]) } ==
 { (BaseAddr[i][38:27] & ~AddrMask[i][38:27]),
 (BaseAddr[i][21:11] & ~AddrMask[i][21:11]) });
```

### D18F2x7C\_dct[0] DRAM Initialization

IF (BootFromDRAM) THEN Cold reset: 0000\_0000h. ELSE Reset: 0000\_0000h. ENDIF. See 2.9.3 [DCT Configuration Registers]. See 2.9.7.8 [DRAM Device and Controller Initialization].

BIOS can directly control the DRAM initialization sequence using this register. To do so, BIOS sets EnDramInit to start DRAM initialization. BIOS should then complete the initialization sequence specified in the appropriate JEDEC specification. After completing the sequence, BIOS clears EnDramInit to complete DRAM initialization. BIOS should not assert LDTSTOP\_L while EnDramInit is set. Setting more than one of the command bits in this register (SendControlWord, SendMrsCmd, and SendAutoRefresh) at a time results in undefined behavior.

| Bits | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | <b>EnDramInit: enable DRAM initialization.</b> Read-write. 1=Place the DRAM controller in the BIOS-controlled DRAM initialization mode. The DCT deasserts CKE when this bit is set. BIOS must wait until D18F2x98_dct[0][DctAccessDone] = 1 before programming AssertCke=1 and DeassertMemRstX=1. BIOS must clear this bit after DRAM initialization is complete. BIOS must not set this bit on a DCT with no attached DIMMs.                                        |
| 30   | Reserved. Read; write-1-only; cleared-by-hardware.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 29   | <b>SendZQCmd: send ZQ command.</b> Read; write-1-only; cleared-by-hardware. 1=The DCT sends the ZQ calibration command with either all even or all odd chip selects active. The first command targets even chip selects. Subsequent commands alternate between even and odd chip selects. This bit is cleared by the hardware after the command completes. This bit is valid only when EnDramInit=1. Rtl hardcoded to send a ZQCL command, MrsAddress has no effect. |
| 28   | <b>AssertCke: assert CKE.</b> Read-write; S3-check-exclude. Setting this bit causes the DCT to assert the CKE pins. This bit cannot be used to deassert the CKE pins.                                                                                                                                                                                                                                                                                                |
| 27   | <b>DeassertMemRstX: deassert memory reset.</b> Read-write; S3-check-exclude. Setting this bit causes the DCT to deassert the memory reset. This bit cannot be used to assert the memory reset pin.                                                                                                                                                                                                                                                                   |
| 26   | <b>SendMrsCmd: send MRS command.</b> Read; write-1-only; cleared-by-hardware. 1=The DCT sends the MRS commands defined by the MrsChipSel, MrsAddress, and MrsBank fields of this register. This bit is cleared by hardware after the command completes. Reserved if D18F2x78_dct[0][AddrCmdTriEn]=1.                                                                                                                                                                 |
| 25   | <b>SendAutoRefresh: send auto refresh command.</b> Read; write-1-only; cleared-by-hardware. 1=The DCT sends an auto refresh command. This bit is cleared by hardware after the command completes.                                                                                                                                                                                                                                                                    |
| 24   | Reserved. Read-write.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 23:21 | <b>MrsChipSel: MRS command chip select.</b> Read-write; S3-check-exclude. Specifies which DRAM chip select is used for MRS commands. Defined only if ( $\sim$ EnDramInit   $\sim$ D18F2x90_dct[0][Unbuf-fDimm]); otherwise MRS commands are sent to all chip selects.<br><div> <div>Bits</div> <div>Description</div> </div> <div> <div>000b</div> <div>MRS command is sent to CS0</div> </div> <div> <div>110b-001b</div> <div>MRS command is sent to CS&lt;MrsChipSel&gt;</div> </div> <div> <div>111b</div> <div>MRS command is sent to CS7</div> </div> |
| 20:18 | <b>MrsBank[2:0]: bank address for MRS commands.</b> Read-write; S3-check-exclude. Specifies the data driven on the DRAM bank pins for MRS commands.                                                                                                                                                                                                                                                                                                                                                                                                         |
| 17:0  | <b>MrsAddress[17:0]: address for MRS commands.</b> Read-write; S3-check-exclude. Specifies the data driven on the DRAM address pins for MRS commands.                                                                                                                                                                                                                                                                                                                                                                                                       |

### D18F2x80\_dct[0] DRAM Bank Address Mapping

IF (D18F2x118[LockDramCfg] &  $\sim$ D18F3x12C[OverrideLockDramCfg]) THEN Read-only. ELSE Read-write. ENDIF. IF (BootFromDRAM) THEN Cold reset: 0000\_000Ah. ELSE Reset: 0000\_0000h. ENDIF. See 2.9.3 [DCT Configuration Registers]. These fields specify DIMM configuration information. These fields are required to be programmed based on the DRAM device size and with information of the DIMM. Table 123 shows the bit numbers for each position.

| Bits  | Description                              |
|-------|------------------------------------------|

**D18F2x84\_dct[0] DRAM MRS**

IF ([BootFromDRAM](#)) THEN Cold reset: 0000\_0005h. ELSE Reset: 0000\_0005h. ENDIF. See [2.9.3 \[DCT Configuration Registers\]](#). The fields of this register are applied to the MRS during HW DRAM initialization.

| Bits  | Description |
|-------|-------------|
| 31:24 | Reserved.   |

| 23                   | <p><b>PchgPDMoSel: precharge power down mode select.</b> Read-write. BIOS: 1. Specifies how a chip select enters and exits power down mode. This mode is enabled by <a href="#">D18F2x94_dct[0][PowerDownEn]</a> and its behavior varies based on the setting of <a href="#">D18F2x94_dct[0][PowerDownMode]</a> and MR0[PPD] in <a href="#">D18F2x2E8_dct[0]_mp[1:0][MxMr0]</a>. This register is applied to the MRS during HW DRAM initialization.</p> <table><tr><th><u>PowerDownMode</u></th><th><u>PchgPDMoSel</u></th><th><u>MR0[PPD]</u></th><th><u>Description</u></th></tr><tr><td>0b</td><td>0b</td><td>0b</td><td>Full channel slow exit (DLL off)</td></tr><tr><td>0b</td><td>0b</td><td>1b</td><td>Full channel fast exit (DLL on)</td></tr><tr><td>0b</td><td>1b</td><td>xb</td><td>Full channel dynamic fast exit/slow exit</td></tr><tr><td>1b</td><td>0b</td><td>0b</td><td>Reserved (Full channel slow exit)</td></tr><tr><td>1b</td><td>0b</td><td>1b</td><td>Partial channel fast exit (DLL on)</td></tr><tr><td>1b</td><td>1b</td><td>xb</td><td>Partial channel dynamic fast exit/slow exit</td></tr></table> <p>See <a href="#">D18F2x248_dct[0]_mp[1:0][Txpdll, Txp]</a>. In dynamic fast exit/slow exit power down mode, the DCT dynamically issues MRS command(s) to the DRAM to specify the powerdown mode; the DCT specifies fast exit mode when chip selects on one of the two CKEs has recently been active; it specifies deep power down when chip selects on all CKEs have been idle. PchgPDMoSel=0 &amp;&amp; MR0[PPD]=1 fast exit modes are reserved if S3 is also supported .</p> | <u>PowerDownMode</u> | <u>PchgPDMoSel</u>                          | <u>MR0[PPD]</u> | <u>Description</u> | 0b  | 0b                   | 0b      | Full channel slow exit (DLL off) | 0b | 0b | 1b | Full channel fast exit (DLL on) | 0b | 1b | xb | Full channel dynamic fast exit/slow exit | 1b | 0b | 0b | Reserved (Full channel slow exit) | 1b | 0b | 1b | Partial channel fast exit (DLL on) | 1b | 1b | xb | Partial channel dynamic fast exit/slow exit |

| 1:0                  | <p><b>BurstCtrl: burst length control.</b> Read-write. BIOS: 01b. Specifies the number of sequential beats of DQ related to one read or write command. Requests from the processor are always 64-byte-length. Requests generated by <a href="#">D18F2x250_dct[0]</a> are always 64-byte-length. Requests from GMC may be 32-byte or 64-byte-length. Software must ensure that GMC requests are disabled to configure the DCT and DRAMs for 8-beat burst length (e.g. during training). If this mode is changed, software must issue a mode-register set command to MR0 of the DRAMs to place them in the same mode.</p> <table><tr><th><u>Bits</u></th><th><u>Description</u></th></tr><tr><td>00b</td><td>8 beats</td></tr><tr><td>01b</td><td>Dynamic 4 or 8 beats</td></tr><tr><td>11b-10b</td><td>Reserved</td></tr></table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | <u>Bits</u>          | <u>Description</u>                          | 00b             | 8 beats            | 01b | Dynamic 4 or 8 beats | 11b-10b | Reserved                         |    |    |    |                                 |    |    |    |                                          |    |    |    |                                   |    |    |    |                                    |    |    |    |                                             |

| 6:2   | Reserved.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1     | <b>ExitSelfRef: exit self refresh (after suspend to RAM or for DRAM training) command.</b> Read, write-1-only; cleared-by-hardware. IF ( <a href="#">BootFromDRAM</a> ) THEN Cold reset: 0. ELSE Reset: 0. ENDIF. Writing a 1 to this bit causes the DRAM controller to bring the DRAMs out of self refresh mode. It also causes the DRAM controller to issue ZQCL and MRS MR0 commands (using DCT internal versions of the MR0 state). This command should be executed by BIOS when returning from the suspend to RAM state, after the DRAM controller configuration registers are properly initialized, or when self refresh is used during DRAM training. This bit is read as a 1 while the exit-self-refresh command is executing; it is read as 0 at all other times. This bit should not be set if the DCT is disabled. |

### D18F2x94\_dct[0] DRAM Configuration High

See [2.9.3 \[DCT Configuration Registers\]](#).

| Bits   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |      |             |    |                                                  |        |                                                                      |

| 16 | <b>PowerDownMode: power down mode.</b> Read-write. IF ( <a href="#">BootFromDRAM</a> ) THEN Cold reset: 0. ELSE Reset: 0. ENDIF. BIOS: 1. Specifies how a chip select or group of chip selects enters power down mode when enabled by <a href="#">D18F2x94_dct[0][PowerDownEn]</a> . A chip select enters power down mode when the DCT deasserts the CKE pin. The command and address signals tristate one MEMCLK after CKE deasserts. The DCT behavior varies based on the setting of <a href="#">D18F2x84_dct[0][PchgPDMoSel]</a> . See also <a href="#">Table 122 [DIMM, Chip Select, and Register Mapping]</a> . <p>0=Channel CKE control mode; the DRAM channel is placed in power down mode when all chip selects associated with the channel are idle; CKE pins for the channel operate in lock step in terms of placing the channel in power down mode.</p> <p>1=Chip select CKE control mode; the chip select group controlled by a CKE pin is placed in power down mode when no transactions are pending.</p> |

### D18F2x98\_dct[0] DRAM Controller Additional Data Offset

Reset: 8000\_0000h. See 2.9.3 [DCT Configuration Registers].

Each DCT includes an array of registers that are used primarily to control DRAM-interface electrical parameters. Access to these registers is accomplished as follows:

Reads:

1. Write the register number to [D18F2x98\\_dct\[0\]\[DctOffset\]](#) with [D18F2x98\\_dct\[0\]\[DctAccessWrite\]](#)=0.
2. Read the register contents from [D18F2x9C\\_dct\[0\]](#).

Writes:

1. Write all 32 bits of register data to [D18F2x9C\\_dct\[0\]](#) (individual byte writes are not supported).
2. Write the register number to [D18F2x98\\_dct\[0\]\[DctOffset\]](#) with [D18F2x98\\_dct\[0\]\[DctAccessWrite\]](#)=1.
  - The data will be delivered to the phy similar to a posted memory-write, and the write will complete without any further action. However, to ensure that the contents of the array register write have been delivered to the phy, software issues a subsequent configuration register read or write to any register in the northbridge. For example, reading [D18F2x98\\_dct\[0\]](#) will accomplish this.

Registers for which there is one instance per memory P-state (listed with “\_mp[1:0]” appended to the register mnemonic) use [D18F1x10C\[MemPsSel\]](#), [D18F2x94\\_dct\[0\]\[DphyMemPsSelEn\]](#), and [D18F2x9C\\_x0D04\\_E008\\_dct\[0\]\[PStateToAccess\]](#) for software accesses. BIOS programs these fields appropriately to ensure consistency of registers with controller fields and DDR phy fields.

- [D18F2x9C\\_x0000\\_0\[3:0\]0\[3:1\]\\_dct\[0\]\\_mp\[1:0\]](#) refers to all instances of the [D18F2x9C\\_x0000\\_0\[3:0\]0\[3:1\]](#) register.
- [D18F2x9C\\_x0000\\_0\[3:0\]0\[3:1\]\\_dct\[0\]\\_mp\[1\]](#) refers to the register for memory P-state 1 of either or both DCTs.
- It is recommended that BIOS program context sensitive registers in batches (training/restoring all registers of a context before selecting a new context). BIOS should do the following prior to a new “batch”:
  - Program [D18F2x94\\_dct\[0\]\[DphyMemPsSelEn\]](#)=1.
  - Program [D18F2x9C\\_x0D04\\_E008\\_dct\[0\]\[PStateToAccess\]](#)=target.
  - Program [D18F1x10C\[MemPsSel\]](#)=target.

Writes to any register in this additional address space causes the FIFO pointers to be reset. Therefore, it is recommended that only BIOS write these registers.

Reads or writes to any register in this additional address space collide with system self-refresh requests. Once power management is enabled software should temporarily disable power management prior to accessing these registers.

| Bits | Description                                                                                                                  |
|------|------------------------------------------------------------------------------------------------------------------------------|
| 30   | <b>DctAccessWrite: DRAM controller read/write select.</b> RAZ; write. 0=Specifies a read access. 1=Specifies a write access. |
| 29:0 | <b>DctOffset: DRAM controller offset.</b> Read-write.                                                                        |

### D18F2x9C\_dct[0] DRAM Controller Additional Data Port

Reset: 0000\_0000h. S3-check-exclude. See [D18F2x98\\_dct\[0\]](#) for register access information. See 2.9.3 [DCT Configuration Registers]. Address: [D18F2x98\\_dct\[0\]\[DctOffset\]](#).

| Bits | Description              |
|------|--------------------------|
| 31:0 | <b>Data.</b> Read-write. |

### D18F2x9C\_x0000\_0000\_dct[0]\_mp[1:0] DRAM Output Driver Compensation Control

See 2.9.7.6.6 [DRAM Address Timing and Output Driver Compensation Control].

### D18F2x9C\_x0000\_0[3:0]0[3:1]\_dct[0]\_mp[1:0] DRAM Write Data Timing

BIOS: See 2.9.7.9.4 [DQS Position Training].

**Table 125:** Index Mapping for D18F2x9C\_x0000\_0[3:0]0[3:1]\_dct[0]\_mp[1:0]

| D18F2x98_dct[0][31:0] | Function                |
|-----------------------|-------------------------|
| 0000_0001h            | DIMM/CS 0 Bytes 3-0     |
| 0000_0002h            | DIMM/CS 0 Bytes 7-4     |
| 0000_0003h            | DIMM/CS 0 ECC           |
| 0000_0101h            | DIMM/CS 1 Bytes 3-0     |
| 0000_0102h            | DIMM/CS 1 Bytes 7-4     |
| 0000_0103h            | DIMM/CS 1 ECC           |
| 0000_0201h            | Reserved/CS 2 Bytes 3-0 |
| 0000_0202h            | Reserved/CS 2 Bytes 7-4 |
| 0000_0203h            | Reserved/CS 2 ECC       |
| 0000_0301h            | Reserved/CS 3 Bytes 3-0 |
| 0000_0302h            | Reserved/CS 3 Bytes 7-4 |
| 0000_0303h            | Reserved/CS 3 ECC       |

**Table 126:** Byte Lane Mapping for D18F2x9C\_x0000\_0[3:0]0[3:1]\_dct[0]\_mp[1:0]

| Register                               | Bits     |          |          |       |
|----------------------------------------|----------|----------|----------|-------|
|                                        | 31:24    | 23:16    | 15:8     | 7:0   |
| D18F2x9C_x0000_0[3:0]01_dct[0]_mp[1:0] | Byte3    | Byte2    | Byte1    | Byte0 |
| D18F2x9C_x0000_0[3:0]02_dct[0]_mp[1:0] | Byte7    | Byte6    | Byte5    | Byte4 |
| D18F2x9C_x0000_0[3:0]03_dct[0]_mp[1:0] | Reserved | Reserved | Reserved | ECC   |

If D18F2xA8\_dct[0][PerRankTimingEn]=1 then the function is CS. Otherwise the function is DIMM. These registers control the timing of write DQ with respect to MEMCLK and allow transmit DQS to be centered in the data eye. The delay starts 1 UI before the rising edge of MEMCLK corresponding to the CAS-write-latency. See 2.9.7.9 [DRAM Training]. WrDatGrossDly must be programmed for a given DIMM and lane such that WrDatDly - WrDqsDly <= 0.5 MEMCLKs.

| Bits      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |      |             |      |                   |         |                                |           |                                |      |                  |

### D18F2x9C\_x0000\_0004\_dct[0]\_mp[1:0] DRAM Address/Command Timing Control

BIOS: 2.9.7.6.6.

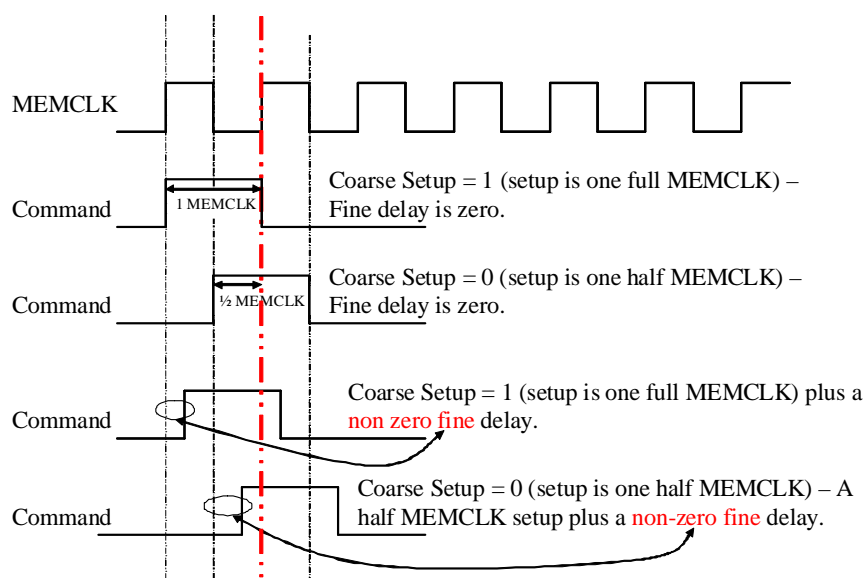

Figure 8: Address/Command Timing at the Processor Pins

This register controls the timing of the address, command, chip select, ODT and clock enable pins with respect to MEMCLK as shown in Figure 8. See 2.9.7.4.2 [DRAM Channel Frequency Change] and 2.9.7.4.3 [Phy Fence Programming]. 2T timing is controlled by D18F2x94\_dct[0][SlowAccessMode]. If a setup time (coarse delay) field is changed and D18F2x94\_dct[0][MemClkFreqVal]=1, then software must toggle MemClkFreqVal for the delay to take effect.

| Bits    | Description                                                                                                                                                                                                                                                                                                                                                                             |      |             |     |                   |         |                                |     |                    |

| D18F2x9C_x0000_0[3:0]07_dct[0]_mp[1:0] | Reserved | Reserved | Reserved | ECC   |

If **D18F2xA8\_dct[0][PerRankTimingEn]**=1 then the function is CS. Otherwise the function is DIMM.

These registers control the timing of read (input) DQS signals with respect to DQ. See 2.9.7.9 [DRAM Training]. Writes to **D18F2x9C\_x0000\_0[3:0]0[7:5]\_dct[0]\_mp[1:0]** set

**D18F2x9C\_x0D0F\_0[F,8:0]2[3:0]\_dct[0]\_mp[1:0][RdDqsTimeU, RdDqsTimeL]** = {RdDqsTime, RdDqsTime}.

Reads from **D18F2x9C\_x0000\_0[3:0]0[7:5]\_dct[0]\_mp[1:0]** return

**D18F2x9C\_x0D0F\_0[F,8:0]2[3:0]\_dct[0]\_mp[1:0][RdDqsTimeL]**.

The actual delay applied to the DQS input signal before sampling data includes an internal part dependent (insertion) delay plus the nominal delay specified by the register setting.

| Bits    | Description                                                                                                                                                                                                                                                                                                     |      |             |     |                   |         |                             |     |                    |

#### **D18F2x9C\_x0000\_0008\_dct[0]\_mp[1:0] DRAM Phy Control**

Cold reset: 0208\_0000h. See 2.9.7.9 [DRAM Training]. This register also provides access to the multiplier and divider values used in the DDR phy. The default values for the given MEMCLK frequency of the PLL when **D18F2x94\_dct[0][MemClkFreqVal]**=1 can be found: [MACOREPLL Spec:1.4.3.1 Suggested DDR Phy Frequency Settings for 100Mhz RefClk].

| Bits | Description                                                                                                                                                                                |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 31   | Reserved. Read-write.                                                                                                                                                                      |
| 30   | <b>DisAutoComp: disable automatic compensation.</b> Read-write. BIOS: See 2.9.7.4.4. 1=Disable the compensation control state machine. 0=The phy automatic compensation engine is enabled. |
| 29   | <b>DisablePredriverCal: disable predriver calibration.</b> Read-write. BIOS: See 2.9.7.4.4. 1=Disable the update of predriver codes to all pads.                                           |

| 13   | <b>DqsRcvTrEn: DQS receiver training enable.</b> Read-write. 1=Initiate hardware assisted read DQS receiver training. The phy waits for back to back read requests from the DCT (using the read pending signal), discards the first 20 UI worth of DQS samples to account for asynchronous read return latency, and enables the PRE for updating using subsequent samples until the read pipeline is interrupted with a deassertion of read pending. At that time, the PRE will stop updating regardless of the state of this bit, and waits for another string of back to back read requests. During the time that the PRE is enabled for sampling, the phy starts in high gain mode, where two samples contribute to one LSB of phase change; this persists for 64 samples. The phy then changes to a low gain mode, where 32 samples contribute to one LSB of phase change. A minimum of 400 samples will assure convergence. This can be accomplished with multiple strings of reads of at least 56 UI. 0=Stop read DQS receiver training. This allows BIOS to reliably read the DQS receiver training data. |      |             |     |                                           |     |                                         |     |                                                                      |     |                                                                      |

| 11b  | TxPad flop (applies to WrDat, WrDqs, and Addr/Cmd/Cs/Odt/Cke timing)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |      |             |     |                                           |     |                                         |     |                                                                      |     |                                                                      |
| 5:4  | <b>TrChipSel: training DIMM select.</b> Read-write; S3-check-exclude. Specifies a timing control for a corresponding rank which is to be trained. If <a href="#">D18F2xA8_dct[0][PerRankTimingEn]</a> =1 then the function is CS. Otherwise the function is DIMM. This field also selects which bit of the x4DIMM field is used (which is then used to determine which nibble is trained). To ensure complete consistency with 45nm product phy based training, if PerRankTimingEn=1 then x4DIMM[] must be zero.<br><table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>00b</td><td>DIMM/CS 0</td></tr> <tr> <td>01b</td><td>DIMM/CS 1</td></tr> <tr> <td>10b</td><td>DIMM:Reserved/CS 2</td></tr> <tr> <td>11b</td><td>DIMM:Reserved/CS 3</td></tr> </table>                                                                                                                                                                                                                                                                                                                                           | Bits | Description | 00b | DIMM/CS 0                                 | 01b | DIMM/CS 1                               | 10b | DIMM:Reserved/CS 2                                                   | 11b | DIMM:Reserved/CS 3                                                   |

This field specifies the fence delay threshold value used to create the fence bit in the DLL delay registers for write data, write DQS, Addr/Cmd, CS, ODT, and CKE. The corresponding fence bit is set by hardware when the DLL delay register is written if DLL delay &gt;= FenceThresholdTxPad.</p> <table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>00h</td><td>0/64 MEMCLK delay</td></tr> <tr> <td>1Eh-01h</td><td>&lt;FenceThresholdTxPad&gt;/64 MEMCLK delay</td></tr> <tr> <td>1Fh</td><td>31/64 MEMCLK delay</td></tr> </table> | Bits | Description | 00h | 0/64 MEMCLK delay | 1Eh-01h | <FenceThresholdTxPad>/64 MEMCLK delay | 1Fh | 31/64 MEMCLK delay |     |                 |

#### **D18F2x9C\_x0000\_000D\_dct[0]\_mp[1:0] DRAM Phy DLL Control**

Cold Reset: 0000\_0000h. This register defines programmable options for the phy's DLLs for power savings. There are two identical sets of configuration registers: one for the transmit DLLs (those running off of the phy's internal PCLK which is running at rate of 2\*MEMCLK) and receive DLLs (those running off of the DQS from the DIMMs). These values are programmed by BIOS based on programmed DDR frequency. This register must be programmed before DRAM device initialization.

| Bits  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

If [D18F2xA8\\_dct\[0\]\[PerRankTimingEn\]](#)=1 then the function is CS. Otherwise the function is DIMM.

Each of these registers control the timing of the receiver enable from the start of the read preamble with respect to MEMCLK. See [2.9.7.9 \[DRAM Training\]](#). These delay registers must be programmed such that across all DIMMs and lanes  $\text{MAX}(\text{DqsRcvEnDelay}) - \text{MIN}(\text{DqsRcvEnDelay}) \leq 7 \text{ UI}$ .

| Bits    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |      |             |     |                   |         |                                     |         |                                     |     |                   |

If [D18F2xA8\\_dct\[0\]\[PerRankTimingEn\]](#)=1 then the function is CS. Otherwise the function is DIMM. Each of these registers control the DQS timing delay for write commands relative to MEMCLK. The delay starts at the rise edge of MEMCLK corresponding to the CAS-writelatency. Each control includes a gross timing field and a fine timing field, the sum of which is the total delay. See [2.9.7.9 \[DRAM Training\]](#).

| Bits      | Description                                                                                                                                                                                                                                                                                                                                             |      |             |      |                   |         |                                |           |                                |      |                  |

### **D18F2x9C\_x0000\_00[52:50]\_dct[0] DRAM Phase Recovery Control**

These registers are used by BIOS for hardware assisted DRAM training. Writes to these registers seed the phase recovery engine prior to training. Reads from the registers indicate how much the phase recovery engine has advanced to align the MEMCLK and DQS edges and is under hardware control. See [2.9.7.9 \[DRAM Training\]](#).

The MSB bit adjusts the DAC current profile that is used only by the delayline, which adjusts the tuning curve of the delayline. The remaining two bits affect the global bias current.<br><table> <tr> <th>Bits</th><th>Description</th></tr> <tr> <td>000b</td><td>-25%</td></tr> <tr> <td>001b</td><td>Nominal</td></tr> <tr> <td>010b</td><td>+50%</td></tr> <tr> <td>011b</td><td>+100</td></tr> <tr> <td>100b</td><td>-25% + delayline adjust</td></tr> <tr> <td>101b</td><td>Nominal + delayline adjust</td></tr> <tr> <td>110b</td><td>+50% + delayline adjust</td></tr> <tr> <td>111b</td><td>+100 + delayline adjust</td></tr> </table> | Bits | Description | 000b | -25% | 001b | Nominal | 010b | +50% | 011b | +100 | 100b | -25% + delayline adjust | 101b | Nominal + delayline adjust | 110b | +50% + delayline adjust | 111b | +100 + delayline adjust |
